Introduction

About ADE

This chapter provides an overview of the Analytica Decision Engine (ADE) and summarizes the information presented in this book.
Introduction

What is the Analytica Decision Engine?

The Analytica Decision Engine (ADE) is a powerful COM component that helps you to access Analytica models via a program. ADE lets you run any Analytica model on a server computer. It provides an Application Programming Interface (API) through which other application programs can create, read, check, parse, evaluate, modify, and save Analytica models. For example, you can create a user interface accessible via a web browser so that users can run Analytica models as web applications. Or you can use ADE to access your Analytica model from another application that can supply inputs, run the model, and collect and display results.

Although you can use ADE to build and edit models with commands issued via the API, it is usually much more convenient to use Analytica Enterprise for this purpose (see the Analytica Tutorial and Analytica User Guide for details, including the “Analytica Enterprise” chapter of the Analytica User Guide). After you have an Analytica model, you can use ADE to build a custom user interface via a web browser or other application, to interface the model with another application.

ADE is provided in two forms so that it is compatible with a wide range of applications. These forms are an ActiveX in-process automation server, Adew.dll, and a COM local automation server, ADE.exe. The classes, methods, and properties exposed by these servers are accessible from any programming environment that supports the use of COM, ActiveX Automation, or .NET interfaces. Such environments include VB, VB.NET, ASP, ASP.NET, C#, Visual C/C++, J#, VB Script, and JavaScript. For example, you can use Visual Basic or C# to create graphical user interfaces (GUIs) on 32-bit Microsoft Windows platforms for your Analytica models, tailored to specific applications and specific classes of end users.

Figure shows a conceptual model of ADE. Your application makes calls to the functions exposed by the interface classes of ADE. Those functions then return information to your application. Server objects allow you to read, check, parse, evaluate, modify, and save Analytica models from within your applications.

Using the ADE server

ADE provides objects of six OLE classes: CALicense, CAEngine, CAObject, CATable, CAIndex, and CARenderingStyle ("CA" stands for Class Analytica). You use these classes to interact with your Analytica model through ADE. The CAEngine class contains methods and properties to open and close existing models, create new models, and access objects in your Analytica model.

It is important to distinguish these OLE object classes in ADE from the Analytica object classes. Analytica classes include chance, decision, index, objective, and variable (which we refer to collectively as variable classes); model, module, and library (which we refer to collectively as module classes); functions, and attributes. You can access Analytica objects as instances of the
**Introduction**

**CAObject** class. This class provides properties and methods to get and set attributes of Analytica objects, including identifier, title, and description, as well as definition and value for variables.

You can access the value of a variable via the **ResultTable** property of class **CATable**. A **CATable** represents an Analytica **array** (also known as a **table**) so that you can get or set its individual elements (also known as **cells**). Each element can be a **number** or a **string** value (termed a **text** value in Analytica).

A **CATable** has zero or more dimensions. Zero dimensions means it is **atomic** (it has a single element). Each dimension is identified by an Analytica index, represented by the **CAIndex** class. A **CAIndex** has a name and a list of labels, numbers, or strings used to identify the rows or columns (more generally, **slices**) of the array. In Analytica, you identify dimensions of an array by name, not by order.

The **CARenderingStyle** class provides control over formatting of returned values as numbers or text.

Before your code can interact with ADE, you must create a **CAEngine** object, from which all else is obtained. You can create a **CAEngine** class directly, or you can first obtain a **CALicense** object, and then use it to create a **CAEngine**. The **CALicense** class can tell you whether your ADE license allows you to create a **CAEngine**, and provide more detailed information about why the **CAEngine** could not be created when a failure occurs.

**How to use this document**

The rest of this guide includes these sections:

**Chapter 1, Installation**
This chapter explains the steps required to install the Analytica Decision Engine 4.5 on your Windows NT 4 (>SP 6), 2000, XP, or Vista computer.

**Chapter 2, The Analytica Decision Engine Tutorial**
This chapter shows you how to use the Analytica Decision Engine (ADE) from within a Visual Basic program, and steps you through building your first ADE application using Visual Basic.

**Chapter 3, Using the Analytica Decision Engine Server**
This chapter provides a step-by-step guide to the functionality accessible through ADE. You should read this section to get better acquainted with the classes, and their methods and properties. By using the sample code fragments presented in this section in your code, you can begin accessing information in your models from your Visual Basic applications immediately.

**Chapter 4, Working with Models, Modules, and Files**
This chapter contains examples of common operations and manipulations you might perform on objects in your Analytica model.

**Chapter 5, ADE Server Class Reference**
This chapter provides reference materials on the six object classes in ADE and their properties and methods, including method syntax, data types, and property access information. Refer to the information in this section after you’ve read through “Chapter 3, “Using the Analytica Decision Engine Server,” and have specific questions about particular methods and properties.
Chapter 1  

Installation

This chapter explains the system requirements for the Analytica Decision Engine (ADE) and describes how to install, upgrade, and uninstall ADE.
System requirements

- 30 MB of hard drive space (you need more space to develop your applications)
- 256 MB of RAM
- You also need a development language environment to build your application using ADE. This could be Visual Studio with VB.NET, C#, ASP.NET, VC++, or any other COM or .NET-enabled development environment. You can also use ADE from Microsoft Office Visual Basic for Applications (VBA) or from Windows Scripting Host (CScript.exe or WScript.exe), as well as other COM-enabled or ActiveX automation-enabled packages.

You can obtain all the files for installation of ADE from the ADE CD-ROM or you can download the installer from http://www.lumina.com/ana/support/download.htm.

The installation contains the ADE in-process automation server (Adew.dll), the ADE local automation server (ADE.exe), auxiliary files needed by ADE, this ADE User Guide, and example programs.

Installing the Analytica Decision Engine files

Installing from the network

Obtain an ADE 4.5 license code from Lumina. This is supplied to you, usually through e-mail, when you purchase ADE. You must complete the installation within three days after the license code is issued to you.

Download the ADE setup executable. The location of the file is provided when you receive your license code. Save the file to disk.

Run (i.e., double click) the file you just downloaded to begin the ADE installer.

Follow the instructions. Read and agree to the license agreement, select a directory for the installation, and enter your license code when prompted.

If the installer reports that your license code is stale, go to http://lumina.com/ADE/staleLicense to obtain a fresh code. After you obtain a fresh code, be sure to enter the license code within three days.

Installing from CD

Insert the Analytica Decision Engine CD into your CD-ROM drive.

If the installer does not automatically start, run the setup.exe program on the CD.

During setup, you need to select a directory for installation, to read and agree to the licensing terms, and to enter the license code supplied to you by Lumina Decision Systems when you acquired ADE.

If the installer reports that your license code is stale, go to http://lumina.com/ADE/staleLicense and obtain a fresh code. After you obtain a fresh code, be sure to enter the license code within three days.

After following the steps above, the following files should exist in the directory in which you installed ADE:

- Adew.dll
- ADE.exe
- Analytica.ini
- Analytica.i
- ODBC4Analytica.dll
- license.txt
- SolverSDK.dll
• readme.txt
• solver.lic

Two ADE manuals are installed into a subdirectory called docs. These are:
• ADE User Guide.pdf (this document)
• ADE Scripting.pdf

Four example programs should also have been installed in that directory underneath the examples directory. They are as follows:

Tutorial.NET — This program is referred to by the Analytica Decision Engine Tutorial. It is recommended that you read the Analytica Decision Engine Tutorial completely before writing your own programs that depend on ADE.

AdeTest — This program allows you to call or test the methods of ADE objects through a GUI. You can run AdeTest.Exe (in the bin directory), or you can trace through the code in the Visual Studio.NET 2005 debugger to observe each method being called.

asp_exam — This program shows you how to access ADE through a Microsoft ASP program.

excel_exam — This program shows you how to access ADE from any application with Visual Basic for Applications (VBA) support, including the Microsoft Office suite of applications.

Entering a new license code

If you have previously installed an earlier version of ADE and need to enter a new (different) license code, follow these steps:

1. If you've installed ADE 4.4 or later:
   a. Start > Programs > Analytica Decision Engine > Configure License.
      A dialog appears prompting you enter your new license code.

2. For pre-4.4 releases:
   a. Open a cmd.exe prompt as administrator:
      E.g., in Windows 7, press Start then type cmd in the search box. Right click on cmd.exe in the items found and select Run As Administrator.
   b. Use the cd command the change to the same directory where you installed the earlier version of ADE.
   c. Type ADE /RegServer
      A dialog appears prompting you enter your new license code.

Upgrading from an earlier version of ADE

ADE 4.5 has been configured to install without disturbing previously installed versions of ADE. This allows you to compare the performance and output of your application under the different versions. However, it also means that your existing applications continue to use the previous version until you have changed them to use ADE 4.5.

Uninstalling ADE

To uninstall ADE, select Add/Remove Programs in the Windows Control Panel. Scroll through the list to find “Analytica Decision Engine 4.5.” Click the Remove button and proceed through the uninstall wizard.
Chapter 2

The Analytica Decision Engine Tutorial

This tutorial shows you how to use the Analytica Decision Engine (ADE) from within a Visual Basic program.
Your first ADE application

First let’s write a simple ADE application from scratch, just to be sure that everything is set up correctly. Follow these steps:

1. Bring up Visual Studio.NET.
2. Select New Project, then select the Project Type “Visual Basic Projects” and the template “Console Application.” Select a project name, e.g., “FirstADEtry,” and an appropriate folder location.
3. From the Project menu, select Add Reference and select the COM tab in the dialog. Find and select Analytica Decision Engine Local Server 4.5 (ade.exe) and click OK.

Note: If you have installed ADE 64-bit and do not have ADE 32-bit installed, Visual Studio may not show Analytica Decision Engine Local Server 4.4, even though it is properly installed. This occurs because Visual Studio itself is a 32-bit application. If this happens, select the Browse tab on the Add Reference dialog, navigate to the ADE install directory (usually C:\Program Files\Lumina\ADE 4.5), and select ADE64.exe.

Note: If you cannot find this entry in the list of COM servers, then ADE 4.5 is not properly installed. See “Installation” on page 5 for instruction on how to install ADE before reading further.

4. Add to the Module1 class as follows:
   Imports ADE
   Module Module1
     Public ADE As CAEngine
     Sub Main()
       Dim FileName, ModelName As String
       FileName = "C:\Program Files\Lumina\Analytica 4.5"
       FileName &= \"\Example Models\Tutorial Models\Car Cost.ana"
       ADE = New CAEngine
       ModelName = ADE.OpenModel(FileName)
       If ModelName = "" Then
         Console.Write(FileName & " not found")
       Else
         Console.Write("Congratulations on opening ")
         Console.WriteLine(ModelName)
         Console.WriteLine("Press 'enter' to exit")
         Console.ReadLine()
       End If
     End Sub
   End Module

5. Now run the program. If your program prints “Congratulations on opening Carcosts” you have just successfully written your first ADE program.

This first program did the following:
- Created a CAEngine automation object called ADE (using New CAEngine).
- Opened an Analytica model (using the OpenModel method of CAEngine).
- Displayed the name of the model (the return value of OpenModel).

We go into the details of these and other functions in the next section.
Chapter 2
The Analytica Decision Engine Tutorial

What’s next?

We will not attempt to explain all of the features of ADE in this tutorial. These are described in the following chapters of this guide. Here, we give you the background to explore the more advanced features of ADE on your own.

From this point, we use the example model called Txc.ana. You can find Txc.ana in the Risk Analysis folder under the Example Models folder installed with Analytica. If you cannot find it, or if you opted not to install the examples when you originally installed Analytica, there is a copy in the Examples\Tutorial.NET folder in the directory where you installed ADE.

The Txc model demonstrates risk-benefit analysis of reducing the emissions of the fictitious air pollutant TXC. Please open the Txc model with Analytica to see how it works.

The example Visual Basic.NET program called TestTxc in your Ade Examples\Tutorial.NET folder shows many aspects of ADE. This program creates an ADE automation object, opens the Txc.ana model with this object, gets the definition of the Population Exposed variable, evaluates the Total Cost variable, prints out the result of the Total cost variable as a table by getting at the individual components of the table, and changes the definition of the Population Exposed variable. It then gets the result of the Total cost variable again, to see what effect the change of definition for Population Exposed had on the Total Cost variable. If things are set up properly, TestTxc displays the window shown in “Text Txc window”.

The application displays the definition of the Population Exposed variable ("Normal (30M, 3M)"), and the table associated with Total Cost, based on the definition of Population Exposed. You can change the definition of Population Exposed by selecting File > Change Population Exposed from the main menu and seeing the effect this has on the Total Cost table.

Text Txc window

Distinguishing title from identifier

Whenever an ADE function requires a variable, you must pass it the identifier of the variable, not its title. This can be confusing since Analytica normally displays the titles of each variable in an influence diagram. By default, when you first create each object, Analytica automatically creates an identifier based on the title. It substitutes an underscore (_) for each blank or other character in the title that is not a letter or number.
You can show the identifiers in an influence diagram by pressing Control+y (or by selecting **Show by identifier** from the **Object** menu). For model *Txc.ana*, you can see that the identifier of the variable titled *Population Exposed* is *Pop_exp*. It is important to use *Pop_exp* as the identifier when passing this variable to ADE functions. ADE would not be able to find the variable if you pass *Population Exposed* instead, and would return an error.

### Creating an ADE object from within Visual Basic

If you haven’t already, load the project called *Examples\Tutorial\TestTxc.sln* into Visual Basic.NET, and view the code for the file called *TestTxc.vb*. The code looks like this:

```vbnet
Imports ADEW

Public adeEngine As CAEngine

Public Sub Main()
    Dim exeDirectory, theModel As String
    Dim theModelString As String
    exeDirectory = VB6.GetPath
    theModel = exeDirectory & ".\" & "Txc.ana"
    adeEngine = New CAEngine
    ...
    theModelString = adeEngine.OpenModel(theModel)
    ...
    frmMain.DefInstance.Show()
End Sub
```

At the very top of the file, the code declares the automation object **adeEngine** as a **CAEngine** object. Using this object, we can access all of the public functions exposed by **CAEngine** (see “ADE Server Class Reference” on page 49 for a complete listing). This line then creates the **CAEngine** object.

**adeEngine = New CAEngine**

The **adeEngine** variable now holds our in-process **CAEngine** object.

If we want to use the local (out-of-process) server version of ADE, we can add a reference to the project to the *Analytica Decision Engine Server 4.5 COM* component and change the top line from **Imports ADEW** to **Imports ADE**.

Here is another way to obtain a new **CAEngine** object. This sequence does not require adding a reference to the project.

```vbnet
adeEngine = CreateObject("ADEW4.5.CAEngine") ' in-process
adeEngine = CreateObject("ADE4.5.CAEngine") ' out-of-process
```

To understand the pros and cons of using an in-process server versus as out-of-process (or local) server, and which automation server to use for different scenarios, see “In-process vs. out-of-process” on page 22, as well as other books related to COM servers.

### COM vs. Automation interface

In the example above, we used a COM interface to call ADE. In a COM interface, the object (**CAEngine** in this case) is declared as **CAEngine**, and the compiler resolves each member function and can detect several obvious errors at compile time. In addition, Visual Studio can provide a list of methods and parameter types as tool tips as you program, which is helpful when writing programs that use ADE. COM calls are slightly faster than Automation calls, but the speed difference is not usually significant in applications of ADE. With ADE 4.5, we recommend using the COM interface if your programming language supports it.

In VB Automation, you can declare an object simply as **Object**, rather than a more specific types such as **CAEngine**, **CAObject**, and so on. When ADE methods are called using Automation, the
methods are resolved at run time. At compile time, the compiler does not know whether your ADE object has a function named OpenModel. In VB, the syntax for calling a COM method or an Automation method is identical — the only difference is whether the object's type is declared explicitly.

In VC++ and C#, the syntax for calling COM is not the same as for Automation. In these cases, COM is much more convenient, while Automation can get rather tedious. However, some languages, including VBScript and other scripting languages, support only Automation and not COM.

**Monitoring the Process**

When using the out-of-process ADE server, your own code must release the CAEngine COM object when it terminates. When this final CAEngine usage is released, the ADE.exe process automatically terminates. In the code seen so far, the VB language takes care releasing the object automatically when it reaches the end of the program. However, while you are debugging your own code, you may terminate your program prematurely to fix a bug, your program may be killed from Task Manager, or your own code may crash, causing your program's process to terminate before it had a chance to release the object. Because the COM object is never released, the ADE.exe process cannot know that it is no longer in use, and you may get zombie ADE.exe processes lingering.

To avoid this, it is a good practice to call CAEngine::MonitorProcess(..) immediately after obtaining a CAEngine instance. You pass the method the process id for your program's own process. In this fashion, ADE can learn which process is using it, and will set up a thread to detect if your process terminates before ADE is fully released. If your program's process does terminate, the ADE process immediately shuts itself down, eliminating the build-up of zombie ADE processes.

To obtain your process ID from a .NET application, use the GetCurrentProcess().Id found in the System.Diagnostics.Process namespace. In other languages, you can use the Windows SDK function GetProcessId().

MonitorProcess() can only be used to monitor processes running on the same computer as ADE's process, so you can't use this if running ADE through DCOM. There is no need to use this when using the in-process ADEW server.

**Opening a model with ADE**

We will now open the Txc.ana model, and show the main window of our application. Use the following call:

```vbscript
theModelString = adeEngine.OpenModel(theModel)
frmMain.DefInstance.Show
```

The OpenModel function of CAEngine opens the model. If successful, the variable theModelString contains the name of the model. Otherwise, it contains an empty string. Although we haven't done so in this example for the sake of brevity, you should check to see that the string returned from OpenModel isn't empty. If it is, there was an error in opening your model. You can find out what kind of error with the ErrorCode and ErrorText properties of CAEngine (adeEngine.ErrorCode and adeEngine.ErrorText). We will see how to use these two properties later on. For a listing of all the error codes, see Appendix A, “Error Codes” on page 72.

**Retrieving objects from the Analytica model**

The next step is to retrieve objects (variables, modules, functions, etc.) from our model, so that we can access their attributes (definition, title, class, etc.). Our example model (Txc.ana) manipulates the Pop_exp and Cost objects. In particular, it modifies Pop_exp to see how this effects the Cost object.
The **PrintAttributes** function in the file `frmMain.frm` of our `TxcTest.vbproj` (`TxcText.sln`) project shows how to do this. This function is first called by the **Form_Load** function of `frmMain.frm`, when the application starts, to display the **Cost** table. It is also called whenever we wish to print out the current result of our **Cost** table. The function looks like this:

```vba
Public Sub PrintAttributes(ByRef inputIdentifier As String, ByRef outputIdentifier As String)
    Dim inputObject, outputObject As CObject
    Dim resultTable As CATable
    Dim definitionAttrInput As String
    inputObject = adeEngine.GetObjectByName(inputIdentifier)
    outputObject = adeEngine.GetObjectByName(outputIdentifier)
    definitionAttrInput = inputObject.GetAttribute("definition")
    resultTable = outputObject.ResultTable
    Call PrintResultTable(resultTable, inputIdentifier, definitionAttrInput, outputIdentifier)
    ReleaseComObject(resultTable)
    ReleaseComObject(inputObject)
    ReleaseComObject(outputObject)
End Sub
```

**PrintAttributes** works with the variable identifiers `Pop_exp` passed as parameter `inputIdentifier` and `Cost` passed as parameter `outputIdentifier`. It fetches the corresponding objects using the **GetObjectByNames** function of **CAEngine** as follows:

```vba
inputObject = adeEngine.GetObjectByName(inputIdentifier)
outputObject = adeEngine.GetObjectByName(outputIdentifier)
```

If **GetObjectByNames** succeeds, it returns an object of type **CAObject**. You then use the functions of **CAObject**. See “SendCommand(command)” on page 54 for a listing all **CAObject** functions. If **GetObjectByNames** fails, the return value is **Nothing**. The code should check to make sure that the result from **GetObjectByNames** is valid. If not, use the **ErrorCode** and **ErrorText** properties of **CAEngine** to get more information about the error. For example:

```vba
If inputObject Is Nothing Then
    MsgBox("This error from GetObjectByName occurred: ",
            vbCrLf & adeEngine.errorCode & ":" & adeEngine.errorText)
Else
    'inputObject valid
End If
```

### Getting object attributes

Each Analytica object has a set of attributes (analogous to properties), such as identifier, title, description, and class. You can use the **GetAttribute** function to obtain an attribute from an Analytica object. For example, to get the definition of `inputObject` (currently, the cost):

```vba
definitionAttrInput = inputObject.GetAttribute("definition")
```

In the `Txc.ana` model, the definition of `Pop_exp` is "Normal (30M, 3M)" which we store in `definitionAttrInput`.

### Evaluating objects and retrieving results

Use **Result** or **ResultTable** methods of **CAObject** to get the value of a variable. ADE automatically evaluates the variable first, if necessary. Use the **Result** method if you are sure the result will be **atomic**, i.e., a single element. Otherwise, use **ResultTable**, which retrieves the result as an
array. An atomic result is treated as a special case of an array, one with zero dimensions. If the value is atomic, the method `AtomicValue` returns its single value as a number or string.

By default, `Result` and `ResultTable` return the *mid* value of the result, i.e., the result of ADE evaluating it as deterministic. For a probabilistic value, set the `ResultType` property of `CAObject` to the desired uncertainty view — Mean, Sample, PDF, CDF, Confidence bands, or Statistics (see “ResultType” on page 58 for details). We get the value of `outputObject` like this:

```csharp
resultTable = outputObject.ResultTable
```

The result is a `CATable` object, which lets us access individual elements in a table.

If you call `Result` to get an array (or table) value, it returns the array as a string, listing the indexes and elements separated by commas. It is usually easier to use `ResultTable`, so that you don’t have to parse elements of the table from the string.

**Getting the index elements of a table**

An Analytica table has zero or more indexes. If it has one index, then it is one-dimensional; if it has two indexes, it is two-dimensional, and so on. A zero-dimensional table holds a single atomic (or scalar) value. You can use the `NumDims` function of `CATable` to get the number of dimensions (same as number of indexes) of a table. To get at the individual indexes of a table, use methods `IndexNames` and `GetIndexObject` of `CATable`.

The function `PrintResultTable` in `frmMain.frm` shows the use of these two functions. `PrintResultTable` is called from `PrintAttributes`, and does the actual work of printing the table that shows up in our `TestTxc` application (for brevity, we show only the parts of this function related to ADE).

```csharp
Public Sub PrintResultTable(ByRef resultTable As CATable, ByRef inputIdentifier As String, ByRef definitionAttrInput As String, ByRef outputIdentifier As String)
    Dim theIndexName, theTableName As String
    Dim theIndexElement As String
    Dim theTableElement
    Dim theIndexObj As CAIndex
    Dim numEls As Integer
    Dim spaces, i As Integer
    Dim lenStr As Short
    Dim OutputStr As Short
    Dim spaceString, underlineString As String
    ...
    theIndexName = resultTable.IndexNames(1)
    theTableName = resultTable.Name
    theIndexObj = resultTable.GetIndexObject(theIndexName)
    numEls = theIndexObj.IndexElements
    ...
    For i = 1 To numEls
        theIndexElement = theIndexObj.GetValueByNumber(i)
        theTableElement = resultTable.GetDataByElements(i)
        ...
    Next i
    InformationPane.Text = outputString
End Sub
```

The lines of `PrintResultTable` that get an index of a table are as follows:

```csharp
theIndexName = resultTable.IndexNames(1)
```
theIndexObj = resultTable.GetIndexObject(theIndexName)

We get the name of first index using the **IndexNames** function of CATable. We pass it into the **GetIndexObject** function of CATable to get a CAIndex object that represents our index. This automation object returns information about its corresponding index. If this function fails, it returns **Nothing**. In that case, use **ErrorCode** and **ErrorText** functions of CAEngine to find out why.

### Getting information from CATable and CAIndex

**PrintResultTable** also shows how to get information from CATable and CAIndex objects. This code gets the index and table elements of the Cost table:

```
numEls = theIndexObj.IndexElements
For i = 1 To numEls
    theIndexElement = theIndexObj.GetValueByNumber(i)
    theTableElement = resultTable.GetDataByElements(i)
    ...
Next i
```

The **IndexElements** property of CAIndex returns the number of elements in the (first) index. The **GetValueByNumber** function of CAIndex gets individual index elements.

To get the individual table elements of the Cost table object, **resultTable**, we use the **GetDataByElements** function of CATable, passing in the coordinates of the element in the table.

When we retrieve an individual element of our CATable object (resultTable), we take advantage of the fact that the table is one-dimensional. Therefore, we only need to pass **GetDataByElements** a single number representing the position in our table. If we were dealing with two or more dimensions, however, we would need to pass **GetDataByElements** an array specifying the coordinates of the element of our table to retrieve. So, if we want to retrieve the element at position (4,3) of a two-dimensional table, we would write:

```
Dim W as Variant 'return element
Dim IndexPtrs(1 To 2) As Variant 'position in table
    ...
IndexPtrs(1) = 4
IndexPtrs(2) = 3
W = resultTable.GetDataByElements(IndexPtrs)
```

### Controlling formats of atomic values

Each atomic value in a CATable can be a number, string, or one of a few other basic types (e.g., Null, Undefined, Reference, or Handle). These are returned as **variants**, a data structure understood by Visual Basic, specifying the type and value. The **RenderingStyle** property of CATable controls how the underlying Analytica value is mapped to the Visual Basic variant.

For example, it can return a numeric value as a number, or a string using the Analytica model’s number format setting. If it is formatted, an option controls whether to truncate the number of digits or to return it with full precision.

In the **PrintResultTable** subroutine, located in **frmMain.vb**, the rendering style is explicitly specified:

```
resultTable.RenderingStyle.NumberAsText = True
resultTable.RenderingStyle.FullPrecision = False
resultTable.RenderingStyle.StringQuotes = 2
```

The first line specifies that numeric values should be formatted as text according to the number format associated with the result object. For example, in the program output, we see **30.103M** instead of **30102995.6639812**, which would likely be displayed if we had let Visual Basic con-
Other ways to access tables

There are several ways to access the elements of a multi-dimensional CATable. Some might be more convenient in certain scenarios than others.

The first way is to use the GetDataByElements or GetDataByLabels methods of CATable, shown in the code example above. In this case, you supply the coordinates of the cell whose atomic value you wish to retrieve.

A second way is to use the Slice or Subscript methods of CATable to obtain a new CATable object having one less dimension. By repeatedly reducing the dimensionality, you eventually reach zero dimensions, in which case you have a single atomic value. At that point, the AtomicValue method of CATable returns this value. The AtomicValue method is the only way to access a scalar value (since it doesn’t have a coordinate). You must use this method if you need to generate a graph image of a slice of the full result.

A third way is to use the GetSafeArray method of CATable, to convert the multi-dimensional array into a safe array (or into a .NET array). You can then manipulate the multi-dimensional array directly in VB or other .NET language. Since there is no inherent ordering to Analytica dimensions, but safe arrays and .NET arrays have an explicit ordering, you must first use the SetIndexOrder of CATable to specify the ordering of dimensions before calling GetSafeArray. Note that this is not necessary if you know that your array is one-dimensional.

Modifying objects

A custom application often gets input from a user or other external source to transfer into input variables in the Analytica model. You can do this either by setting the definition of an input variable, or by using a definition table.

TestTxc shows how to modify the definition of Pop_exp, which is a model input that effects the Cost result variable. To set the definition in the example, select File > Change Population Exposed from the main menu. A dialog appears, as shown in .

Redefining the variable definition

Enter a new definition into the field and click Ok. The main window displays the new value of Cost. The OkButton_Click function in ChangeDef.frm is called when the Ok button is clicked in the dialog. It modifies the definition of Pop_exp, and then calls the PrintAttributes function that prints the result of Cost.

The function looks like this:

```vba
Private Sub OkButton_Click(ByVal eventSender As System.Object, ByVal eventArgs As System.EventArgs) Handles OkButton.Click
    Dim errorText As String
```
Dim pop_exp_Object As CAObject
Dim errorCode As Short
Dim errorString As String
newDefinition = PopExposedDef.Text
pop_exp_Object = adeEngine.GetObjectByName("pop_exp")
pop_exp_Object.SetAttribute("definition", newDefinition)
errorCode = adeEngine.errorCode
If errorCode <> 0 Then
    MsgBox("This error occurred while processing your definition:
" & vbCrLf & vbCrLf & adeEngine.errorText)
    PopExposedDef.Focus()
Else
    Me.Close()
    frmMain.DefInstance.PrintAttributes("Pop_exp", "Cost")
End If
ReleaseComObject(pop_exp_Object)
End Sub

This function grabs the new definition typed into the New Definition for Population Exposed field and sets it to the Pop_exp object by using the SetAttribute function of CAObject object. It then calls PrintAttributes, which evaluates the Cost object, and prints the new table.

To set a new definition for the pop_exp variable, we get the CAObject for Pop_exp, and set its definition to the definition typed in by the user. This is done with the following code:

    pop_exp_Object = adeEngine.GetObjectByName("pop_exp")
    pop_exp_Object.SetAttribute "definition", newDefinition

Whenever you call SetAttribute, you should check the ErrorCode of the CAEngine automation object (adeEngine), in case the definition is illegal.

Try entering a new definition such as Uniform(25M,35M) and click Ok. When the definition of pop_exp is changed, the result for Cost gets recomputed by ADE when ResultTable is next called for the Cost variable (when the application window is repainted).

Graphing with ADE

Using the same graphing engine used by Analytica 4.5, you can generate a chart or graph to display an array-valued or uncertain result. In ADE 4.5, you can use the GraphToFile and GraphToStream methods of CATable. The graphs are returned in several possible image formats, such as image/png, image/bmp or image/jpeg.

The easiest way to select from the available graphing options is to open your model with Analytica. You can experiment with the settings for the various defaults or override selected variables to see how they look. When you've chosen the settings you want, save the model. ADE then uses these settings when producing result graphs for each variable.

For higher-dimensional results, some work might be necessary to select the slice of the result that will be plotted and the specific pivot (i.e., which dimensions appear on the X-axis versus in the key). The Subscript or Slice methods of CATable can be used to select the particular slice to be plotted and SetIndexOrder can be used to control the pivot. See “Class CATable” on page 61 for details. In our Tutorial.NET example, we have a one-dimensional result (Cost), and do not need to worry about slicing or pivoting.

The GraphToStream method is used to transfer the graph image directly from ADE to a user-interface method. GraphToStream is a bit more complicated to use than GraphToFile, since GraphToFile requires little more than a file name to write the image to. To use GraphToStream,
we must set up a stream in memory, allow ADE to write to that stream, and then reconstitute the image from that stream. Because .NET streams are not compatible with COM streams, you need to use the StreamConnector class provided with ADE. The GraphResult_Click routine in frmMain shows the use of GraphToStream. Select the Graph Result menu option from the main application window, and the results appear in a graph as shown in .

![Result graph](image)

### Conclusion

In this tutorial, we introduced several important aspects of the Analytica Decision Engine. We saw how to create the ADE server object, open a model with ADE, get at an individual object in a model, evaluate objects, access elements in a table, and modify objects in a model. But, ADE can do a lot more!

We hope that you have learned enough about the basics so that you can now explore the more advanced features on your own. We recommend that you now read the rest of this guide to learn about what ADE can do.
Chapter 3

Using the Analytica Decision Engine Server

This chapter describes the Analytica Decision Engine server classes CAEngine, CALicense, CAObject, CATable, CAIndex, and CARenderingStyle, and the server class architecture.
ADE classes

ADE uses the following six classes:

- The **CAEngine** class contains methods and properties that allow you to open and close existing models, create new models, create new Analytica objects, and access Analytica objects contained in your model.
- The **CALicense** class contains methods that allow you to instantiate a **CAEngine**, to use a special application license code, to examine certain restrictions on your ADE license, and to access details about why a **CAEngine** failed to instantiate.
- The **CAObject** class contains methods and properties that allow you to set and obtain information about the Analytica objects (such as variables or modules) that you obtain from the **CAEngine** class.
- The **CATable** class is used to examine multi-dimensional results or to view and modify multi-dimensional definition tables (also called *edit tables*).
- A **CAIndex** object provides access to one dimension of a multi-dimensional **CATable**.
- The **CARenderingStyle** class is new in ADE 4.0, and allows you to control or alter the format in which ADE returns values.

*Note:* "CA" in these class names stands for "Class Analytica."

The following sections describe how to access these Analytica Server objects from Visual Basic or C#.

Server class architecture

COM, Automation, and .NET

ADE 4.5 supports two calling conventions: COM and ActiveX Automation. COM is an early-binding convention in which the methods and data types are resolved when your application code is compiled. Automation is a late-binding convention where method calls are resolved at run time. The COM convention is somewhat more efficient, although for most applications, the difference in efficiency is far overshadowed by the time required to compute your model's results.

In Visual Basic, the syntax for calling a method using COM or Automation is identical, and which interface is used depends on how you declare your objects. In other languages, such as C# or C++, the method of invocation can look quite different. In C# and C++, it is generally more convenient to use the COM interface. VBScript (used by the Windows Scripting Host and older versions of IIS ASP) supports only the Automation interface.

The COM interface can be used transparently from a .NET environment such as Visual Studio 2005. The .NET programming environment wraps COM objects with a .NET Interop object, which gives ADE interfaces the appearance of being .NET interfaces.

In ADE 3.1 and before, the Automation interface was the recommended convention; however, with the ADE 4.5 release, we now recommend the COM interface unless this is not an option in your programming environment (such as VBScript).

In-process vs. out-of-process

ADE can be launched either in-process or out-of-process. When launched in-process (ADEW), the adew.dll library is loaded into your application’s process space. When launched out-of-process (ADE), the ade.exe server is launched and runs in a different process. Both types of server use the same class interfaces, so the choice of which type of server to use can usually be changed by editing a single line of code, i.e., the line that instantiates the **CAEngine**.

In-process servers have a slight performance advantage, but come with several restrictions. First, the apartment threading model of ADEW must be compatible with your application’s threading model. For example, The Microsoft IIS web server (IIS 5.0 or later) does not allow you to use an apartment-threaded component under its default settings. Also, you are restricted to have only one **CAEngine** instance (and thus, only one model) in memory at any one time.
Out-of-process instances of ADE run in a different process, and can be configured to run on a different computer from your application. Because data must be "marshaled" across process boundaries, it is less efficient, but it is far more flexible than the in-process server. Your program can make use of multiple simultaneous instances of ADE, each with a separate model instance loaded. As such, the out-of-process server is almost always preferred for web applications because you can have one ADE instance for each session.

Typescript

In addition to the program interface, ADE has a fully functional command interface, known as the typescript language. This language is described in the Analytica Scripting Guide. This language allows access to all of ADE’s functionality. The API provides a more convenient, object-oriented set of functions for communication with the engine from Visual Basic and C++ applications. A calling program can use the API functions, or it can pass typescript commands directly to the typescript interface.

Security permissions under IIS

When creating a web application that uses ADE from within Microsoft's Active Server Pages (ASP/ASPX) under Internet Information Server (IIS), you might need to configure permission settings in order to instantiate and access the ADE COM component from your program.

When creating a web application or web service, you should use the out-of-process ADE server. When your ASPX application is executed while serving a web page request, the ADE COM component is launched and accessed from a special internal Windows account name. Even though your programs can create and access ADE when run under your account, the same access might not exist for ASP or ASPX programs. To configure security permissions so that your ASPX application can use ADE, follow these steps:

1. From the Windows Control Panel, select Administrative Tools > Component Services.

   **Note:** If you are using ADE 32-bit on a Windows 64-bit machine, then you must instead run:
   ```
   mmc comexp.msc /32
   ```

2. In the DCOM Config folder, locate “Analytica Decision Engine Local Server 4.5.”

3. Select Properties from the right mouse menu, and select the Security tab.

4. Set Launch and Activation Permissions to Customize, then click Edit.

5. Grant local launch and local activation permissions for the account used by IIS. In IIS 5 this is usually {computer_name}\ASPNET. In IIS 6 & 7 this is usually NETWORKSERVICES or IIS_IUSRS. In IIS 7.5, these should be set for the Application Pool name, which is usually "IIS AppPool\DefaultAppPool".

6. Save these settings. You might need to reboot of the machine to finalize these changes.

When these permissions are not properly configured, a "security exception" occurs on the line of your program that attempts to instantiate the CAEngine.
The AdeTest program

ADE 4.5 ships with a sample program called AdeTest.exe. The executable can be found in the Examples/AdeTest/bin directory. You can use AdeTest to exercise the functionality of either the in-process (Adew.dll) or the local process (ADE.exe) versions of ADE 4.5. Using AdeTest, you can send script commands to the engine, create ADE objects, and set or call virtually any of the properties and methods of the ADE objects. If you have Visual Studio 2005 installed, you can step through the code in the Visual Studio Debugger to observe the methods being called.

shows the AdeTest program dialog. The left-hand pane shows a list of ADE objects that the program is currently holding. The right side shows details of one of those objects. In the figure, there are three CAEngine instances, each with a different model open. The first CAEngine is an in-process (Adew.dll) instance, while the second two are out-of-process local servers (ADE.exe) instances. The two buttons above the left pane can be used to create additional CAEngine instances, while the Release button at the lower-right corner of the right-hand panel releases an instance. The right-hand panel shows information about the third CAEngine instance. The current values for the CAEngine properties ErrorCode, ErrorText, CurrentModule, OutputBuffer, and Photo are displayed. You can execute a typescript command by typing the command into the text box and clicking the Send button. Or you can execute any of the method of CAEngine by selecting the method in the drop-down Method box, filling in the parameters, and clicking the Execute Method button.

If you click an object in the left-hand pane, the properties for that object are displayed on the right-hand side and you can set its properties or call its methods. Thus, you can simulate a series of steps your program might execute through the graphical interface.

When a method returns an object, for example, as with CAEngine::GetObjectByName, the returned object is added to the tree on the left as a child of the object that created it. After executing a method from a class other than CAEngine, it is a good idea to glance at the corresponding CAEngine’s panel to check the ErrorCode, ErrorText, and OutputBuffer properties.

The Photo checkbox in the Analytica window is mirrored by the Photo property of the CAEngine class. By default the Photo property is False, so typescript communications between the client and ADE are not copied to the Analytica log window. Setting the Photo property to True copies all subsequent typescript communications between the client and ADE. In Visual Basic, this would be done as follows:

ADE.Photo=True
Turning on the Photo property significantly slows down communication with ADE.

Sample application in Excel’s Visual Basic

Another example program called excel_exam is also included in the ADE package. The program, Analytica.xls, in the excel_exam directory can be loaded into Microsoft Excel and executed as a macro. This program demonstrates the use of Visual Basic for Applications in Excel for ADE communications. This sample makes use of the local server version of ADE.

Sample ASP web application

The example in asp_exam demonstrates the use of ADE from an Active Server Pages web application. This application produces a hierarchical outline of your model structure in HTML. The readme.txt file in that directory contains instructions for configuring the web server to run the example.

When using Microsoft’s ASP, we recommend that you use the local server. By using the local server (ADE.exe), you can ensure that each web application, or even each session, uses a different version of ADE.exe. Currently, there is a limitation in ADE that prevents creation of two or more in-process server objects at the same time. Therefore, if you expect to have more than one session of ADE active at one time (as is almost always the case in web-based applications), always use the local server of ADE.

Using the ADE COM interface

From a .NET project in Visual Studio 2005

From a Visual Basic, C#, J#, ASP.NET, or C++/CLR project in Visual Studio 2005, you gain access to ADE by adding a reference to it in your project. The same technique holds with slight variations in older (pre-.NET) versions of Visual Basic and several other non-Microsoft development environments.

In Visual Studio 2005, select Add reference or References from the Project menu, and in the dialog that appears, select the COM tab (in VC++ you need to click the Add new reference button to get to the COM tab). In the list of components, locate and select one of the following:

- Analytica Decision Engine Local Server 4.5
- Analytica Decision Engine Server 4.5

For out-of-process ADE.exe servers, select the Local server. To use Adew.dll, select the (non-local) server. It is also possible to add both references into a project (the AdeTest example does this), although the need for this would be rare.

The ADE classes are exposed in the name space ADE or ADEW for the local server and in-process server, respectively. For convenience, you can add a using declaration to the top of your source files, like this:

```csharp
Imports ADE ' Visual basic
using ADE;    // C#
using namespace ADE;    // C++/CLR
import ADE.*;    // J#
```

Of course, when using the in-process server you would type ADEW in place of ADE above. These declarations allow you to refer to CAEngine, CAObject, etc., in your code, rather than ADE.CAEngine, ADE.CAObject, etc., which makes it easy to convert from the local to the in-process ADE server should the need arise.
To begin using ADE, you need to obtain a first instantiation of `CAEngine`. This is done with one of the following lines:

```vbnet
dim ADE as CAEngine = new CAEngineClass   ' VB
CAEngine ADE = new CAEngineClass();       // C#, J#
CAEngine^ pAde = gcnew CAEngineClass();   // C++/CLR
```

`CAEngine` is the name of a particular abstract interface, while `ADEW.CAEngineClass` and `ADE.CAEngineClass` are the names of two particular object classes that implement that interface. The `CAEngineClass` object is the only object that you can create directly; all other ADE object instances are obtained by calling methods on existing objects.

To keep the use of the COM interface, always declare your variables with the class names `CAEngine`, `CAObject`, `CATable`, `CAIndex`, and `CARenderingStyle`. Avoid assigning object instances to variables declared as `System.Object`. This allows the compiler to perform early binding and type checking.

### Releasing objects in .NET

In pre-.NET Visual Basic and scripting languages, the programming environment automatically ensures that COM objects are released immediately. This is not the case in VB.NET, ASP.NET, or other .NET programs. From .NET, it is important that your program explicitly releases each COM object when it is through with it. Setting a pointer to Null (or Nothing) is not sufficient, since the actual release doesn't occur until the next garbage collection.

To release a COM object from a .NET program, you need to execute code similar to the following (C# syntax shown):

```csharp
System.Runtime.InteropServices.Marshal.ReleaseComObject(ADE);
ADE = null;
```

Releasing objects in this fashion is especially important when you are using an out-of-process COM server (e.g., `ADE.CAEngine`). In this case, the memory resources are predominantly consumed in the ADE process, not in your program's process. This can cause the ADE process to run out of memory before your program's process uses enough memory to cause an automatic garbage collection to occur. From a .NET-based web application, old `ADE.exe` processes linger long after a session has finished unless you explicitly release the `CAEngine` object.

This need to release COM objects is not unique to ADE. You must take care to release any COM object, including those provided by Microsoft, especially when those COM objects are out-of-process.

Because of this absence of deterministic destruction in .NET, it can be tedious to ensure that every COM object is released. Therefore, you might want to occasionally force an explicit garbage collection in your code, which releases all unused objects. This can be accomplished by calling:

```csharp
System.GC.Collect();
```

### From an ATL project in C++

To use ADE 4.5 from a non-.NET C++ project, place the following two lines at the top of your source file:

```c++
#import "ADE.exe"
using namespace ADE;
```

Or to use the in-process server, use these lines:

```c++
#import "Adew.dll"
using namespace ADEW;
```

You need to include the ADE home directory in your include path in the project settings, or spell out the complete path in the `#import` declaration.

Next, obtain the first instance to an ADE engine using this code:
CoInitialize(NULL);
CAEnginePtr pAde(__uuidof(_CAEngine));
.
.
.
CoUninitialize();

CoInitialize() is a Windows system call that is required before the COM system can be used. If your project spans multiple code files, use this in each of your source files (or once in stdafx.h):

#import "ADE.exe" no_implementation

And then in one file only (e.g., stdafx.cpp), include this line:

#import "ADE.exe" implementation_only

Using the ADE Automation interface

VBScript is an example of a scripting language, usable from Windows Scripting Host (CScript.exe or WScript.exe), pre-.NET versions of Active Server Pages, Internet Explorer, and so on. JScript is another, and many other scripting OLE-Automation compliant scripting languages are available including Perl.

These scripting languages support ActiveX Automation scripting, but not COM interfaces. Using the Automation interface, ADE can be used from these, often with no additional tools beyond a simple text editor.

For ADE releases prior to 4.5, the Automation interface was the preferred convention to use. For languages that support direct COM calls, the COM convention is now recommended in ADE 4.5. Using Automation from C++ or C# is rather tedious and not covered here.

From Visual Basic or VBScript

To use the Automation interface, it is not necessary to add a reference to your Visual Basic project. The syntax here is similar in other scripting languages. In Visual Basic, the code to instantiate a CAEngine is:

    dim ADE as Object
    ADE = CreateObject("ADE4.CAEngine")

In VBScript, and some older versions of Visual Basic, the set keyword is required:

    dim ADE
    set ADE = CreateObject("ADE4.CAEngine")

For the in-process server, you send the parameter ADEW4.CAEngine to the CreateObject call.

ADE typescript: command language communication

The Command property and Send method of the CAEngine class allow you to use typescript commands, sent as ASCII strings to the engine, and receive the resulting output as another ASCII string. You might want to use a typescript command instead of an API method if:

- You want to perform your own parsing on ADE output (e.g., on tabular data that are output from the Analytica Decision Engine as text strings of comma-delimited text).
- No appropriate API method exists.

You perform these steps to send a typescript command to ADE:
1. Assign a text string containing the command to the **Command** property of your **CAEngine** object.

2. Use the **Send** method to send the command to the Engine. If the **Send** method returns **True**, then the command was processed without error by ADE.

3. Store the error code and error text (if the return code is nonzero). These two pieces of information are stored in the **CAEngine** properties **ErrorCode** and **ErrorText**.

4. Get the output by calling the **OutputBuffer** function in the **CAEngine** class.

**Note:** You can also combine the first two steps by calling **CAEngine.SendCommand(cmd)**.

These steps are demonstrated below for various programming languages. After these simple examples, subsequent examples are given using a Visual Basic syntax, but you should have no problem extrapolating the syntax to your language of choice.

### In Visual Basic

```vb
Imports ADE
Module Module1
    Sub Main()
        Dim Result, ErrT As String
        Dim ErrCode As Integer

        Dim ADE As CAEngine = New CAEngineClass
        ADE.Command = "news" 'any typescript command
        Dim SendCode As Boolean = ADE.Send
        If SendCode = False Then
            ErrCode = ADE.ErrorCode
            ErrT = ADE.ErrorText
        Else
            Result = ADE.OutputBuffer
        End If
    End Sub
End Module
```

### In VBScript

```vbscript
set ADE = CreateObject("ADE4.CAEngine")
ADE.Command = "news"
If ADE.Send = False Then
    ErrCode = ADE.ErrorCode
    ErrT = ADE.ErrorText
Else
    Result = ADE.OutputBuffer
End if
```

### In C#

```csharp
using System;
using ADE;
namespace ADE_from_Csharp
{
    class Program
    {
        static void Main()
        {
            String errT, result;
            int errCode;
            CAEngine ADE = new CAEngineClass();
            ADE.Command = "news";
```
if (!ADE.Send()) {
    errCode = ADE.ErrorCode;
    errT = ADE.ErrorText;
} else {
    result = ADE.OutputBuffer;
}

In J#  
import ADE.*;
public class Program
{
    public static void main( )
    {
        String errT, result;
        int errCode;
        ADE.CAEngine ADE = new ADE.CAEngineClass();
        ADE.set_Command("news");
        boolean sendRes = ADE.Send();
        if (!sendRes) {
            errCode = ADE.get_ErrorCode();
            errT = ADE.get_ErrorText();
        } else {
            result = ADE.get_OutputBuffer();
        }
    }
}

In C++/CLR  
using namespace System;
using namespace ADE;
void main( )
{
    String ^result, ^errT;
    int errCode;
    CAEngine^ ADE = gcnew CAEngineClass();
    ADE->Command = "news";
    if (!ADE->Send()) {
        errCode = ADE->ErrorCode;
        errT = ADE->ErrorText;
    } else {
        result = ADE->OutputBuffer;
    }
}

In VC++ (without .NET)   
#import "ADE.exe"
using namespace ADE;
void main( )
{
    CoInitialize(NULL);
    _bstr_t errT, result;
    int errCode;
    _CAEnginePtr pAde(__uuidof(_CAEngine));
    pAde->Command = "news";
if (!pAde->Send()) {
    errT = pAde->ErrorText;
    errCode = pAde->ErrorCode;
} else {
    result = pAde->OutputBuffer;
}
CoUninitialize();

Errors and error handling

The CAEngine properties ErrorCode and ErrorText should be queried after any operation with ADE whenever an error is possible. Reading a value of a property from an ADE object does not change the error code. Setting the value of a property might result in an error, usually indicating an illegal value for that property. All method calls reset ErrorCode to zero if there is no error, or to a value indicating the error.

To get additional information on an error, check the OutputBuffer property of CAEngine. Any error messages that a user of Analytica would have seen appear in the output buffer.
This section contains examples of common operations and manipulations you might perform on objects in your Analytica model.
Models and modules

**Note:** In VBScript, VBA, and pre-dot-NET versions of Visual Basic, the Set keyword was necessary when assigning an object to a variable. In VB.NET, the Set keyword is no longer necessary. The Set keyword is not used in the examples below.

- To create a new model:
  ```vbnet
  If ADE.CreateModel("NewModelName") Then
    'Model successfully created
  End If
  ```

  The `CreateModel` method only requires one parameter, a string containing a model name.

- To open an existing Analytica model:
  ```vbnet
  Dim ModName as String
  ModName = ADE.OpenModel("C:\...\Anamodel.ana")
  If ModName="" then
    'Handle Error condition here
  End if
  ```

  If a model has already been opened, that model is closed automatically before the new model is created. If the specified filename is not legal, `OpenModel` returns an empty string. In that case, use the `ErrorCode` property of `CAEngine` to determine the cause of the error. Be aware that an `ErrorCode=2` warning is often returned even though the load is successful. For full details as to what has caused an error or warning, use the `OutputBuffer` property of the `CAEngine`. You must use the backward slash (\) for the path delimiter when using ADE. It does not support the forward slash (/).

- To add a module from a file to the currently open model:
  ```vbnet
  Dim Merge as Boolean = True
  Dim ModName as String
  ModName = ADE.AddModule ("C:\...\MyLibrary.ana", Merge)
  if ModName="" Then
    'Handle error conditions here
  End if
  ```

  The `FileSpec` parameter should contain the path and filename of the module to be included. The `Merge` parameter is a Boolean variable that determines whether preexisting objects with identical names are overwritten. If `Merge=True`, then conflicting variables are overwritten. If `Merge=False` and there are conflicting variables, then the call to `AddModule` fails.

- To read a script file:
  ```vbnet
  If ADE.ReadScript("C:\..\MyScript.ana") Then
    'Script successfully read
  End If
  ```

  A script file can contain a list of typescript commands. Upon loading the file, the engine executes the commands contained in the file. Errors encountered while running the script file are described in the `ErrorText` property.

- To save a module (i.e., a subset of the current model) in a separate file:
  ```vbnet
  If ADE.SaveModuleFile ("MyLibrary", "C:\...\MyLibrary.ana") Then
    'Save succeeded
  End If
  ```

  The first parameter is the module identifier, the second is the file name.

- To save the current model in a file:
  ```vbnet
  If ADE.SaveModel("C:\...\MyNewModel.ana") Then
    'Save succeeded
  End If
  ```
• To close the current model without saving:
  
  If ADE.CloseModel() Then ... ' Close succeeded

The CloseModel method takes no parameters.

ADE objects

• To create a new CAObject object:
  Dim ObjName As String = "NewVariable"
  Dim ObjClass As String = "Variable"
  Dim var As CAObject = ADE.CreateObject(ObjName, ObjClass)

  The object name and the class of the object to be created are passed into the CreateObject method. Note that an identifier and not the title of the object should be used when giving the object a name. Most object-related methods use their Identifier attribute, not their Title attribute. ADE can create the following types of objects: variable, module, chance, constant, decision, index, and objective. Refer to the Analytica User Guide for more information on these object types.

• To delete an Analytica object from a model:
  Dim obj as CAObject
  If ADE.DeleteObject(obj) Then ... ' Successful

• To set the active module:
  ObjName = "ModuleToMakeActive"
  ObjClass = "Module"
  Var = ADE.CreateObject (ObjName, ObjClass)
  ADE.CurrentModule = Var

ADE uses a hierarchy to order objects. When an object is created, it is created inside the current module. By default, all objects are placed within the top-level module unless you set the Current Module property.

• To identify the current module:
  Dim module As CAObject = ADE.CurrentModule

• To obtain a CAObject object when you know the name of an Analytica variable (this is probably the most commonly used method in ADE):
  Dim Var As CAObject = ADE.GetObjectByName ("IdentifierInModel")
  If Var Is Nothing Then
    'Analytica model associated with Ana
    'does not contain variable with
    'identifier "IdentifierInModel"
  End If

  The method CAObject::Get is synonymous with GetObjectByName.

• You can get all Analytica object attributes using the GetAttribute method:
  UnitsOfVar = Var.GetAttribute ("Units")

  Use the SetAttribute method to change an attribute of an Analytica object:
  If Var.SetAttribute ("definition","A/B") Then
    'Attribute Set Correctly
  Else
    'Attribute Not Set
  End If

• To access or rename the identifier of an object, use the Name property:
  Dim oldName As String = Var.Name
  Var.Name = "NewIdentifier"
Retrieving computed results

The CAObject class contains three methods that cause results to be computed and returned. The Result method evaluates an object in your model and returns the result as a single value. This is most useful if you know that the result is a single number or single text string. The Result-Table method evaluates an object in your model and returns the result as a CATable object. Methods and properties of the CATable object allow you to understand what dimensions are present and to access individual elements (cells). The Evaluate method processes an arbitrary expression and returns the result of parsing and evaluating that expression as a multi-dimensional CATable.

When retrieving results, you have control over which computation mode is used to compute the result. You can compute the deterministic mid point value, or the various probabilistic views: Mean, Sample, PDF, CDF, Statistics, or Bands. Set the ResultType to indicate which result type you desire (default is Mid).

Whether you are computing a scalar or a table, your program eventually accesses individual atomic values such as numbers or text strings. You can use various RenderingStyle settings to control the form in which these values are returned. For example, numeric values can be returned as floating point numbers, formatted strings, or full-precision string depictions. Textual strings can be returned with or without surrounding quotes.

• To evaluate and obtain a simple result (e.g., a scalar) of an object, use the Result method of CAObject:
  Dim Obj As CAObject
  Dim Result
  Obj = ADE.GetObjectByName("ObjectToEvaluate")
  Result = Obj.Result
  If ADE.ErrorCode = 0 Then
    'Result was successfully retrieved
  Else
    'An error occurred
  End If

By default, the Result property of CAObject retrieves the midpoint result of the object. It returns the result as a variant (or in .NET, as a System.Object). This method is convenient for retrieving the results of objects that evaluate to a scalar.

• To evaluate and obtain the result of an object as something other than the midpoint, use the ResultType property of CATable or CAObject:
  Dim Obj As CAObject = ADE.GetObjectByName("ObjectToEvaluate")
  Dim Result
  Obj = ADE.GetObjectByName("ObjectToEvaluate")
  Obj.ResultType = 1 ' get result as mean
  Result = Obj.Result
  If ADE.ErrorCode = 0 Then
    'Result was successfully retrieved as a mean
  Else
    'An error occurred
  End If

The ResultType property is used to indicate the type of result that Result should return. Possible values are 0=Mid point, 1=Mean, 2=Probabilistic Sample, 3=PDF, 4=CDF, 5=Statistics, and 6=Probability Bands. When ResultType>=2, the result is always a table, even if the mid and mean are scalars. See the next section for a discussion on retrieving table results.

• To retrieve a formatted result, set properties of the object’s RenderingStyle:
Dim Obj As CAObject = ADE.GetObjectByName("ObjectToEvaluate")
Dim Result
Obj.RenderingStyle.NumberAsText = true
Obj.RenderingStyle.StringQuotes = 2 ' double quotes.
Result = Obj.Result
If ADE.ErrorCode = 0 then
    ' Result was successfully returned.
End If

In this example, numbers are returned as formatted text using the object's number format property. Strings are returned surrounded by double quotes. So, for example, the numeric value 1.2K might be returned as the string "$1,200.00" if the number format happens to be fixed point, two digits, with trailing zeros, thousand separators, and currency. This numeric value is returned as a text string because the NumberAsText property is True. The string would be returned as ""$1,200.00"" with two extra double quote characters in the result string. This is controlled by the StringQuotes property (0 = no quotes, 1 = ' single quotes', 2 = "double quotes").

Retrieving multi-dimensional results

Before describing how to obtain results from table objects (arrays with one or more dimensions), let us briefly discuss the conceptual model of a table in Analytica.

An Analytica table has the following components:

- Indexes, each of which identifies a dimension of the table
- Values in the cells of the table
- Index labels, which identify the coordinates of each cell

The number of indexes determines the dimensionality of the table. So, for example, if a table contains two indexes, then the table is two-dimensional.

The number of elements in the index determines the actual number of cells in the table. Suppose table T is composed of two indexes, I and J. If I has five elements (AA, BB, CC, DD, and EE) and J has three elements (A, B, and C), then T is either a 5x3 table, or a 3x5 table, depending on your perspective.

Determining your perspective of a table is very important when working with ADE. It is up to you to tell ADE how you wish to view the table. So, for example, in the paragraph above, if you tell ADE to use index I first, followed by index J, then element 2,3 would be the element described by position I=B, J=CC. If, however, you tell ADE to use index J first, followed by index I, then element 2,3 would be described by position I=C, J=BB (note that tables in ADE are 1-based; that is, each dimension goes from 1 to N where N is the size of the index). The method called SetIndexOrder, described below, allows you to set the order of the indexes for your table so that you can look at the table in any way you desire.

The ADE methods are very flexible in terms of how you refer to individual elements in the table. You can either refer to the individual elements by their position number or by their label names. So, for example, you can tell ADE to give you the element at position 2,1 (2 along the first index, and 1 along the second index), or you can tell ADE to give you the element described by 'BB', 'A' where 'BB' and 'A' are label names in their respective indexes. The methods most commonly used for these types of transactions (GetDataByElements and GetDataByLabels) are described below.

As discussed in the previous section, the Result and ResultType methods are used to evaluate and obtain the result of an object. For objects that evaluate to multi-dimensional results, however, it is often inconvenient to use the Result method because the output would be a long comma-delimited string in the following form:

Table Index1...IndexN [Value1, Value2...]
Here, Index1 to IndexN are the indexes of the table, and Value1 to ValueN are the values in the table (which are filled in row by row). So, if we wanted to get at a particular element in the table after using the Result method, we would have to parse through the comma-delimited string returned from Result to get at the element of interest. Fortunately, ADE provides an ADE object of type CATable that provides methods to simplify the manipulation of tables.

- To evaluate and obtain the result of an object as a table use the ResultType method of CAObject:
  ```vba
  Dim Obj As CAObject = ADE.GetObjectByName("MultiDimObject")
  Dim TableResult As CATable = Obj.ResultTable
  If Not (TableResult Is Nothing) Then
    'Result table was successfully retrieved
  Else
    'An error occurred
  End If
  ``

  The ResultTable method of CAObject returns an automation object of type CATable. CATable contains various methods that allow you to set, retrieve, and manipulate individual elements in the table. More than likely, the first thing that you want to do after retrieving the CATable object is to set the index order of the result table.

- To parse and evaluate an arbitrary expression, use the Evaluate method of CAObject.
  ```vba
  Dim Obj As CAObject = ADE.GetObjectByName("ContextObject")
  Obj.ResultType = 2 ' Sample
  Dim TableResult As CATable = Obj.Evaluate("Normal(X,Y^2) / Z")
  If ADE.ErrorCode <> 0 Then
    'An error occurred
  Else
    'Evaluation successful
  End If
  ```

  To use Evaluate, you must first obtain a CAObject instance. Although the expression you are evaluating might have nothing to do with any specific object, the CAObject serves a couple of purposes. First, the ResultType property of the object provides a place to specify the result type that you want computed. Second, if you make use of the NumberAsText rendering style, the number format stored with the indicated object determines how the numbers are formatted. Often, however, the object you use is of no consequence; you can even use the top-level model object as your context object.

  Comparing the previous two examples demonstrates also that there are often two ways to detect failure. The ErrorCode property is non-zero if an error occurred during the evaluation of a method. And for many methods, the return value is Nothing or False if it fails.

- To set the index order of a CATable object, use the SetIndexOrder method:
  ```vba
  Dim Obj As CAObject
  Dim TableResult As CATable
  Dim IndexOrder (2) as String
  Set Obj = ADE.GetObjectByName("MultiDimObject")
  Set TableResult = Obj.ResultTable
  If Not (TableResult Is Nothing) Then
    IndexOrder (1) = "Index2"
    IndexOrder (2) = "Index1"
    If TableResult.SetIndexOrder(IndexOrder)Then
      'Index Order set successfully
    Else
      'An error occurred in setting index order
  ```
End If
Else
  'An error occurred
End If

The code above assumes that we are manipulating a two-dimensional table. We set the index order of this table so that Index2 is the first index, and Index1 is the second index.

In some computer languages, the first element of an array is considered position 0 (zero-based), and in other languages it is position 1 (one-based). Analytica’s Slice function, and the ADE methods are one-based. Older versions of Visual Basic are one-based, while current versions of Visual Basic and most other modern programming languages are zero-based. In the example above, the Visual Basic array was declared and used as follows:

```vbnet
Dim IndexOrder(2) As String
IndexOrder (1) = "Index2"
IndexOrder (2) = "Index1"
```

In modern Visual Basic, this declares an array that ranges from position 0 to position 2 — an array having three elements. Because the first element was not set, it contains the special value Empty. ADE can recognize whether zero-based or one-based arrays are being passed to it. So, depending on your preference, it would work equally well to use a zero-based version, for example:

```vbnet
Dim IndexOrder(1) As String
IndexOrder (0) = "Index2"
IndexOrder (1) = "Index1"
TableResult.SetIndexOrder(IndexOrder)
```

- To retrieve an element in a table by index order, use the GetDataByElements method:

```vbnet
Dim Obj As CAObject
Dim TableResult As CATable
Dim IndexOrder (2) As String
Dim Pos (2) As Integer
Dim Element
Obj = ADE.GetObjectByName ("MultiDimObject")
TableResult = Obj.ResultTable
If Not (TableResult Is Nothing) Then
  'Result table was successfully retrieved
  IndexOrder (1) = "Index2"
  IndexOrder (2) = "Index1"
  RetValue = TableResult.SetIndexOrder (IndexOrder)
  If RetValue = True Then
    'Index Order set successfully
    Pos (1) = 2
    Pos (2) = 1
    Element = TableResult.GetDataByElements (Pos)
    If ADE.ErrorCode = 0 Then
      'element retrieved successfully
    Else
      'an error occurred
    End If
  Else
    'An error occurred in setting index order
  End If
Else
  'An error occurred
End If
```
Retrieving computed results

This code uses **GetDataByElements** to retrieve the element at position \( \text{Index2}=2, \text{Index1}=1 \) and stores the result to **Element**.

- To retrieve an element in a table by index labels, use the **GetDataByLabels** method:

  ```vba
  Dim Obj As CAObject
  Dim TableResult As CATable
  Dim IndexOrder (2) As String
  Dim Pos (2) As String
  Dim Element
  Obj = ADE.GetObjectByName ("MultiDimObject")
  TableResult = Obj.ResultTable
  If Not TableResult Is Nothing Then
    IndexOrder (1) = "Index2"
    IndexOrder (2) = "Index1"
    If TableResult.SetIndexOrder(IndexOrder) Then
      Pos (1) = "SomeLabelInIndex2"
      Pos (2) = "SomeLabelInIndex1"
      Element = TableResult.GetDataByLabels (Pos)
      If ADE.ErrorCode = 0 Then
        'element retrieved successfully
      Else
        'an error occurred
      End If
    Else
      'An error occurred in setting index order
    End If
  Else
    'An error occurred
  End If
  ``

  The code above uses **GetDataByLabels** to retrieve the element at position \( \text{Index2}="\text{SomeLabelInIndex2}" , \text{Index1}="\text{SomeLabelInIndex1}" \) and stores the result to **Element**.

- To control the format of elements obtained by **GetDataByLabels**, **GetDataByElements**, **AtomicValue**, or **GetSafeArray** methods, set **CATable**'s **RenderingStyle** properties:

  ```vba
  Dim TableResult as CATable = Obj.ResultTable
  Dim rs As CARenderingStyle = TableResult.RenderingStyle
  rs.NumberAsText = True
  rs.FullPrecision = True
  rs.UndefValue = ""
  rs.StringQuotes = 1
  Dim Element
  If TableResult.SetIndexOrder(Split("Index2;Index1",";")) Then
    Element = TableResult.GetDataByLabels( _
      Split("SomeLabel1,SomeLabel2","",""))
    If ADE.ErrorCode=0 Then
      ' Element retrieved successfully
    End If
  End If
  ```
• To retrieve the whole table into a Visual Basic or .NET array in one call, use the `GetSafeArray` method:

```vba
Dim Obj As CAObject
Dim TableResult As CATable
Dim IndexOrder (2) As String
Dim Pos (2) As Integer
Dim TheWholeTable

Obj = ADE.GetObjectByName ("MultiDimObject")
TableResult = Obj.ResultTable
If Not (TableResult Is Nothing) Then
    'Result table was successfully retrieved
    IndexOrder (1) = "Index2"
    IndexOrder (2) = "Index1"
    If TableResult.SetIndexOrder(IndexOrder) Then
        'Index Order set successfully
        TheWholeTable = TableResult.GetSafeArray
        If ADE.ErrorCode = 0 Then
            'table retrieved successfully
        Else
            'An error occurred
        End If
    Else
        'An error occurred in setting index order
    End If
Else
    'An error occurred
End If
```

The code above uses `GetSafeArray` to store the entire table in `TheWholeTable`. The elements of each dimension associated with the table returned from `GetSafeArray` are indexed 1 to N, where N is the length of the dimension. The lower bound of the safe array can be changed to zero using this code prior to calling `GetSafeArray`:

```vba
TableResult.RenderingStyle.SafeArrayLowerBound = 0
```

The syntax for reading a multi-dimensional result in a .NET array in C# is worth mentioning:

```csharp
Array theWholeTable = (Array) tableResult.GetSafeArray();
```

• To determine the number of dimensions of the table, use the `NumDims` property:

```vba
NumDimensions = ADE.Get("MultiDimObject").ResultTable.NumDims
```

• To get the index names associated with the table, use the `IndexNames` method:

```vba
Dim CurIndexName As String
Dim Obj As CAObject = ADE.GetObjectByName ("MultiDimObject")
Dim TableResult As CATable = Obj.ResultTable
Dim NumDimensions As integer = TableResult.NumDims
Dim I as Integer
For I = 1 To NumDimensions
    CurIndexName = TableResult.IndexNames(I)
    MsgBox "Current index is " & CurIndexName
Next I
```

The `IndexNames` method returns the index names of the table in the order specified to `SetIndexOrder`. If `SetIndexOrder` has not been set for the `CATable`, then the default order of the indexes is returned.

• To associate `CAIndex` objects with your table, use the `GetIndexObject` method of `CATable`:
Dim Obj As CAObject = ADE.GetObjectByName ("MultiDimObject")
Dim Res As CATable = Obj.ResultTable
Dim NumDimensions As Integer = Res.NumDims
Dim CurIndexName As String = Res.IndexNames(NumDimensions)
Dim IndexObj As CAIndex = Res.GetIndexObject(CurIndexName)

The example above retrieved the last CAIndex object, with respect to the index order, from the table. The CAIndex object provides properties and methods that allow you to obtain information about the respective index.

- To get the number of elements in the index, use the IndexElements property:
  Dim Obj As CAObject = ADE.GetObjectByName ("MultiDimObject")
  Dim Res As CATable = Obj.ResultTable
  Dim NumDimensions As Integer = Res.NumDims
  Dim CurIndexName As String = Res.IndexNames(NumDimensions)
  Dim IndexObj As CAIndex = Res.GetIndexObject(CurIndexName)
  Dim NumElsInIndex As Integer = IndexObj.IndexElements

- To get an index label at the specified position in the index, use the GetValueByNumber method:
  Dim I As Integer
  Dim Obj As CAObject = ADE.GetObjectByName ("MultiDimObject")
  Dim Res As CATable = Obj.ResultTable
  Dim NumDimensions As Integer = Res.NumDims
  Dim CurIndexName As String = Res.IndexNames(NumDimensions)
  Dim IndexObj As CAIndex = Res.GetIndexObject(CurIndexName)
  Dim Str As String = "The elements in the index are: " & vbCrLf
  For I=1 To IndexObj.IndexElements
    Str = Str & IndexObj.GetValueByNumber(I) & " 
  Next I
  MsgBox Str

- To get at the position of an index label in an index, use the GetNumberByValue method:
  Dim Obj As CAObject = ADE.GetObjectByName ("MultiDimObject")
  Dim Res As CATable = Obj.ResultTable
  Dim IndexName As String = Res.IndexNames(Res.NumDims)
  Dim IndexObj As CAIndex = Res.GetIndexObject (IndexName)
  Dim IndexPosition As Integer
  IndexPosition = IndexObj.GetNumberByValue("SomeIndexLabel")
  If ADE.ErrorCode = 0 Then
    'the index position was successfully retrieved
  Else
    'an error occurred
  End If

- To obtain the scalar value in a zero-dimensional array:
  Dim Res As CATable = ADE.Get("SomeObject").ResultTable
  Dim x As Object
  If Res.NumDims = 0 Then
    x = Res.AtomicValue
  Else
    'Handle the array case.
  End If

Sometimes, it is not possible to know in advance whether the evaluation of an object returns
Retrieving computed results

Chapter 4 Working with Models, Modules, and Files

a multi-dimensional result or a scalar. In this case, use ResultTable. If the result happens to be a scalar, NumDims returns zero. In this case, the so-called “array” isn’t an array at all, but rather contains a single atomic value. It is also possible to end up with a zero-dimensional array after calling the CATable::Slice or CATable::Subscript methods. To obtain the atomic value, use the CATable::AtomicValue method.

• To reduce dimensionality in Slice and Subscript operations:

  Dim PandL As CATable = ADE.Get("P_n_L_Statement").ResultTable
  Dim CatIndex As CAIndex = PandL.GetIndexObject("Categories")
  Dim Expenses As CATable = PandL.Subscript(CatIndex,"Expenses")
  Dim Year As CAIndex = Expenses.GetIndexObject("Year")
  Dim InitialExpense
  InitialExpense = Expenses.Slice(Year,1).AtomicValue

The Slice and Subscript methods of CATable return a new CATable object with the number of dimensions reduced by one. These methods are similar to the Slice and Subscript functions built into Analytica. Slice returns the Nth slice (by position) along a given dimension. Subscript returns the slice corresponding to a specified index value.

Creating tables and setting values in tables

We can apply the same methods described above to definition tables to retrieve values from result tables. A definition table, as the name suggests, is when the definition of an object is a Table function (also known as an edit table in Analytica).

The value of an Analytica variable (accessed via ResultTable) can be an array — not because it was defined by a definition table, but simply because it is defined as an expression or function that returns an array value.

When using an edit table, you need to pay careful attention to whether you are passing general expressions into each table cell, or just literal strings. The RenderingStyle.GeneralExpression property determines how string values that you send to the table are interpreted. By default, GeneralExpression=true, which means that if you set a cell value to the string "Revenue", this is an actual expression consisting of one variable identifier, and not a literal string. If you are populating a definition table with literal constants (as you might an input table to your model), you should either use RenderingStyle.GeneralExpressions=false, or remember to prepend and append quotation marks on all literal string values.

An object defined as a definition table does not necessarily produce the same table when ResultTable is called. After all, the definition table can be defined to be an array of identifiers. When ResultTable is called, each identifier’s result is evaluated, and a new table is produced (which would be different than the definition table). If identifiers evaluate to arrays, the result table might have more dimensions than the definition table.

• To get the definition table of an object as a CATable, use the DefTable method of CAObject:

  Dim Obj As CAObject
  Dim TableDef As CATable
  Obj = ADE.GetObjectByName("MultiDimObject")
  TableDef = Obj.DefTable
  If Not TableDef Is Nothing Then
    ’Definition table was successfully retrieved
  Else
    ’An error occurred, or definition is not a table
  End If

After the definition table is retrieved, we can use all the same methods described in the section above (GetDataByElements, GetDataByLabels, SetIndexOrder, etc.) to retrieve elements in the table and to obtain information about the indexes in the table. We can also
use the same method that we used above in determining whether the result of the object was multi-dimensional or scalar to determine whether the definition of the object is a table or scalar:

```vba
Dim Obj As Object
Dim TableDefinition As Object
Dim ScalarDefinition

Obj = ADE.GetObjectByName ("SomeObject")
TableDefinition = Obj.DefTable
If TableDefinition Is Nothing Then
    ScalarDefinition = Obj.GetAttribute ("definition")
    If ADE.ErrorCode = 0 Then
        ‘you have a scalar definition
    Else
        ‘an error occurred
    End If
Else
    ‘you have a table definition
End If
```

- To set an element in a table by index order, use the `SetDataByElements` method of `CATable`:

```vba
Dim Obj As CAObject
Dim TableDef As CATable
Dim IndexOrder (2) As String
Dim Pos (2) As Integer
Dim Element
Obj = ADE.GetObjectByName ("MultiDimObject")
TableDef = Obj.DefTable
If Not TableDef Is Nothing Then
    ‘Definition table was successfully retrieved
    IndexOrder (1) = “Index2"
    IndexOrder (2) = “Index1"
    If TableDef.SetIndexOrder (IndexOrder) Then
        ‘Index Order set successfully
        Pos (1) = 2
        Pos (2) = 1
        Element = “’ABC’” ‘ Notice the extra quotes
        If TableDef.SetDataByElements(Element,Pos) Then
            ‘element successfully set
            If TableDef.Update Then
                ‘model successfully updated
            Else
                ‘error updating def in model
            End If
        Else
            ‘an error occurred
        End If
    Else
        ‘An error occurred in setting index order
    End If
Else
```

```vba
End If
Else
```
This code uses `SetDataByElements` to set the element at position `Index2=2, Index1=1` to `Element`. Note the use of the quotes around `ABC`. Here, since `ABC` is single quoted, we are putting the string “ABC” in the table. If we instead set `Element` to “ABC”, then the expression `ABC` would be placed in the table. In the latter case, `ABC` would likely be a variable. If an identifier, `ABC`, did not exist in the model, then an error would have occurred while trying to set the element in the latter case. The code then used `Update` to update the model with the new definition. It is important to note that the model containing the object is not updated until `Update` is called. Therefore, if `Update` is not called, and the result of a node that depends on this object is later calculated, the old definition of this object is still used. The other important thing to note is that `Update` functions very differently for result tables than for definition tables. For result tables, `Update` retrieves the result from the specified object again. Therefore, it overwrites any changes that were made to the object using `SetDataByElements` and `SetDataByLabels`.

To set an element in a table by index labels, use the `SetDataByLabels` method of `CATable`:

```vba
Dim Obj As CAObject
Dim TabDef As CATable
Dim IndexOrder (2) as String
Dim Pos (2) as String
Dim Element
Obj = ADE.GetObjectByName("MultiDimObject")
TabDef = Obj.DefTable
If Not TabDef Is Nothing Then
  'Definition table was successfully retrieved
  TabDef.RenderingStyle.GeneralExpression = False
  IndexOrder (1) = "Index2"
  IndexOrder (2) = "Index1"
  If TabDef.SetIndexOrder(IndexOrder) Then
    'Index Order set successfully
    Pos (1) = "SomeLabelInIndex2"
    Pos (2) = "SomeLabelInIndex1"
    Element = "ABC"
    If TabDef.SetDataByLabels(Element,Pos) Then
      'element set successfully
      If TabDef.Update Then
        'model successfully updated
      Else
        'an error occurred
      End If
    Else
      'an error occurred
    End If
  Else
    'An error occurred in setting index order
  End If
Else
  'An error occurred, or definition is scalar
End If
```

The code above uses `SetDataByLabels` to set the element at position `Index2="SomeLabelInIndex2", Index1="SomeLabelInIndex1"` to `Element`. In this example, the `RenderingStyle.GeneralExpression` property was set to `False`. This
Adjusting how values are returned

Analytica models can contain several different data types for values in attributes or in the cells of a table or index. Data types include floating point numbers, textual strings, the special values Undefined and Null, references, and handles to other objects. When these data types are
returned and ultimately mapped to data types in the programming language you are using, you might want or need to alter how the values are returned. You can do so using 

**RenderingStyle**.

The 

**CAObject**, **CATable**, and **CAIndex** objects all contain a property called 

**RenderingStyle**, which returns a 

**CARenderingStyle** object. Properties of the rendering style can be changed to alter how values are returned. You can also control whether safe arrays returned by Analytica are 1-based or 0-based. These settings impact 

**CAObject::GetAttribute**, **CAObject::Result**; they also impact 

**CATable::GetDataByElements**, **CATable::GetDataByLabels**, **CATable::AtomicValue**, **CATable::GetSafeArray**, and **CAIndex::GetValueByNumber**.

When transferring values to cells in a 

**DefTable**, you can also control whether the cells are populated by literal strings and values, or by general expressions. This is controlled by the 

**GeneralExpression** property of 

**CARenderingStyle**.

The 

**DefaultRenderingStyle** and 

**DefaultDefTableRenderingStyle** properties of 

**CAEngine** can be set once just after the 

**CAEngine** has been instantiated to set the rendering style globally. For example, if you always use zero-based arrays, this can be specified once.

- Retrieving numeric values as numbers:
  
  ```
  obj.RenderingStyle.NumberAsText = False
  Dim x As Double = obj.Result
  ```
  
  Numeric values are returned as numbers by default, so unless 
  **NumberAsText** is set to True at some point, there is no need to specify this explicitly.

- Retrieving numeric values as formatted strings:
  
  ```
  Dim TableResult As CATable = Obj.Evaluate("1 / 3 * 10 ^ 6")
  TableResult.RenderingStyle.NumberAsText = True
  TableResult.RenderingStyle.FullPrecision = False
  Dim s As String = TableResult.AtomicValue
  ```
  
  The number format associated with 
  **Obj** is used to format the numeric value. A suffix style with four digits returns “333.3K” for this example.

- Retrieving numeric values as strings with no loss of precision:
  
  ```
  Dim TableResult As CATable = Obj.Evaluate("1 / 3 * 10 ^ 6")
  TableResult.RenderingStyle.NumberAsText = True
  TableResult.RenderingStyle.FullPrecision = True
  Dim s As String = TableResult.AtomicValue
  ```
  
  Analytica continues to use the number format associated with 
  **Obj**, but the significant digits is increased to avoid any loss in precision. So, suffix, exponential, fixed point, and percent formats are not truncated. If a date, integer, or Boolean format is used, some truncation might still occur. In the example, the return value would be 333.333333333333.

- Retrieving string results without quotation marks:
  
  ```
  tab.RenderingStyle.StringQuotes = 0
  ```

- Retrieving string results with explicit quotation marks:
  
  ```
  tab.RenderingStyle.StringQuotes = 1 ' for single quotes
  tab.RenderingStyle.StringQuotes = 2 ' for double quotes
  ```

- Using a custom value for **Undefined**:
  
  ```
  ADE.DefaultRenderingStyle.UndefValue = ""
  ```

  By default, the special value **Undefined** is returned as a the special Windows variant type **Empty**. There are some scripting languages that cannot deal with the **Empty** data type, so if you encounter this problem, you might want to change this value.

- Setting the cells of a definition table to string values:
  
  ```
  defTab.RenderingStyle.GeneralExpression = False
  defTab.SetDataByElements("A & B",inds)
  ```

  In this example, the indicated table cell is set to the string value "A & B". When this table is evaluated, this cell’s result is a string containing the five characters "A & B".
• Setting the cells of a definition table to expressions:
  ```csharp
  defTab.RenderingStyle.GeneralExpression = True
  defTab.SetDataByElements("A & B",inds)
  ```

Here the cell is set to the expression "A & B". When this table is evaluated, the variable named A and the variable B is evaluated, and their results are coerced to strings and concatenated by the & operator.

You can set table cells to literal strings with GeneralExpression=True, but you must embed explicit quotations marks in the expression. For example:

```csharp
  defTab.RenderingStyle.GeneralExpression = True
  defTab.SetDataByElements("'A & B'",inds)
  GeneralExpression=True by default.
```

### Terminating an in-progress computation

Methods such as CAObject.ResultTable, CAObject.Result, or CAObject.Evaluate can initiate lengthy evaluations that could tie up your application. Some models can take many minutes, or even several hours, to compute the result. Normally, your call to ResultTable does not return until the result is fully computed.

You might want to provide your end user with the capability to abort the current computation, such as when a "break" key or button is pressed. Alternatively, you might want to terminate the current computation if your application is suddenly being terminated while a lengthy computation is still processing, so that ADE also terminates.

To implement the ability to abort a computation, you need to have some form of multi-threading in your application. The thread that calls ADE is occupied waiting for ADE to return, so some other thread in your application must detect the request to terminate the computation. When this request is detected, the second thread communicates this request to ADE through a global system event object. You must obtain the information required to locate this global event object from ADE before you have started the length computation. Each CAEngine instance has its own event object with a unique global name, but the same event object applies to the same CAEngine instance for the entire lifetime of the CAEngine instance.

To obtain the event object (using Windows Platform SDK calls):

```csharp
  Dim abortEventName As String
  Dim abortHandle as Handle ' This needs to be global
  ade.SendCommand("GetProcessInfo('Abort Event Object')")
  abortEventName = ade.OutputBuffer
  abortHandle = OpenEvent(EVENT_MODIFY_STATE, FALSE, abortEventName )
  ...
' Launch the computation
  tab = obj.ResultTable
```

In a separate thread that detects a request to terminate the computation, the following code sends that request to ADE (using Windows Platform SDK calls):

```csharp
  SetEvent(abortHandle)
```

Note that OpenEvent and SetEvent are Windows Platform SDK calls, not part of ADE. Also notice that the abortHandle variable must be a global that is accessible from both threads. However, the second thread does not require access to the ADE objects themselves. Alternatively, the abortEventName can be shared and the second thread can call OpenEvent.

When the event has been flagged, ADE backs out of the current computation and returns from the current method. A small delay might be experienced while ADE backs out of the current computation. When it has returned, the CAEngine.ErrorCode is set to 78 ("Computation aborted"). Your application might continue using the same ADE instance as it would have prior to the call that was aborted.
Instantiating CAEngine using CALicense

To start using ADE, the first thing you need to do is instantiate a CAEngine object. You have the option of instantiating your CAEngine object directly, or you can instantiate a CALicense object first and use it to instantiate your CAEngine object. When you’ve successfully obtained a CAEngine object, it doesn’t matter which of these two methods you used to get it. The difference is that if you use a CALicense object to instantiate your CAEngine, more information about why it failed is available. In particular, if the failure is due to a license code problem, your application has an opportunity to handle the error gracefully.

If you are creating an ADE-based application that are to be redistributed to many end users, who would otherwise not have an ADE license, you need to make arrangements with Lumina to license ADE for distribution with your application. This form of licensing requires your application to provide a special type of license code to ADE, called an application license code, since your end users usually do not have a license code of ADE on their computer. Note that a license to redistribute ADE in this fashion is not included as part of the standard ADE license agreement, and additional license fees apply. To use an application license code, you must use a CALicense to instantiate your CAEngine, since your application uses the CALicense object to supply the license code to Analytica.

The steps for instantiating a CAEngine using a CALicense are as follows, e.g.:-

' In VB
Imports ADE
...
Dim license As CALicense = New CALicense
Dim ade As CAEngine = license.NewCAEngine
If (ade Is Nothing) Then
    ' substitute error handling routine here
    ReportError(license.ErrorText)
End If

// In C#
Using ADE;
...
CALicense license = new CALicense();
CAEngine ade = license.NewCAEngine();
if (ade==null) {
    ReportError( license>ErrorText );
}

If you have an application license code, insert a call to SetApplicationLicenseCode:

license = new CALicense
license.SetApplicationLicenseCode("1234-5678-ABCD-EFGH-IJKL")
ade = license.NewCAEngine

Using the Analytica Graphing Engine

When you have a CATable result with at least one dimension, you can obtain a graph of the result as an image. One use of this is to embed graphs as JPEG images in a web page that uses ADE on the back end.

Obtaining the graph of a result requires the following steps:

1. Select the appropriate graph settings, such as chart type, axis range settings, colors, fonts, and so on. The easiest way is to open the model in Analytica Enterprise, and select the settings you want for each variable using the Graph Setup dialog.

   The graph template you create using the Graph Setup dialog is stored in the GraphSetup
attribute of the object. You can copy the GraphSetup attribute from an existing variable if you need to change the style template.

2. From ADE, obtain a CATable with the result to be graphed.

3. Set the GraphWidth and GraphHeight properties of the CATable object to indicate the desired size of the graph in pixels.

4. If your result has more than two dimensions, call Slice or Subscript to reduce the dimensionality to the desired dimensionality for the plot (usually one dimension if there is no key or two dimensions if there is a key).

5. If you have more than one dimension, call SetIndexOrder to select the desired pivot for the graph.

6. If you are sending the graph to an output stream, obtain a Windows IStream interface to the stream. If you have a .NET Stream (System.io.Stream), you need to use a wrapper class (see below).

7. Call either the GraphToStream or GraphToFile methods of CATable, depending on where you want the graph written to. The graph can be created in different MIME types (e.g., image/JPEG).

If you are able to view the result graph in Analytica with no slicers, then steps 4 and 5 are unnecessary.

- Writing a result graph to a file:
  ```vba
  Dim res As CATable = obj.ResultTable
  res.GraphWidth = 640
  res.GraphHeight = 400
  If res.GraphToFile("C:\Temp\Result.JPG","image/JPEG") Then
    ' success
   End If
  
  - Dynamically generating a result graph from an ASP.NET web page:
    ```vbscript
    <% 
    Response.ContentType = "image/JPEG"
    Dim varName As String = Request.QueryString("var")
    Dim ADE As CAEngine = Session("ADE") ' assume existing session
    Dim res As CATable = ADE.Get(varName).ResultTable
    res.GraphWidth = 640
    res.GraphHeight = 400
    Dim stream As StreamConnector = _
      new StreamConnector( Response.OutputStream)
    If res.GraphToStream( stream, "image/JPEG") Then
      ' success
     End If
    %>
    
In this example code, Response, Request, and Session are Active Server Page objects. The HTTP in the client browser would contain a tag like this:

```html
<img src="http://www.acme.com/Myapp/graph.aspx?var=Profit">
```

When Microsoft introduced .NET, they did not make the base Stream class interface in .NET compatible with the IStream interface in Windows. Because of this, it is necessary to create a stream wrapper that implements the IStream interface around the .NET Stream before passing it to GraphToStream. This wrapper, class StreamConnector, is included in the example AdeTest. To use the example above, add the file StreamConnector.vb to your project.
Chapter 5

ADE Server Class Reference

This chapter lists the properties and methods for the six ADE server classes CAEngine, CALicense, CAObject, CATable, CAIndex, and CARenderingStyle.
ADE server classes

The five ADE server classes are **CAEngine**, **CAObject**, **CATable**, **CAIndex**, and **CARenderingStyle**. They are listed below in that order, with a complete description of the properties and methods of each class.

### Class CAEngine

#### Properties

**Command**

<table>
<thead>
<tr>
<th>Description</th>
<th>Sets a typescript language command for execution by the ADE Automation Server. The Send method causes Command to be sent to ADE for execution. For the list of typescript commands, see the Analytica Scripting Guide.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>string</td>
</tr>
<tr>
<td>Access</td>
<td>read/write</td>
</tr>
<tr>
<td>Usage</td>
<td>ADE.Command = “value obj1”</td>
</tr>
</tbody>
</table>

**CurrentModule**

<table>
<thead>
<tr>
<th>Description</th>
<th>The currently open module.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>CAObject</td>
</tr>
<tr>
<td>Access</td>
<td>read/write</td>
</tr>
<tr>
<td>Usage</td>
<td>Dim Obj As Object Set Obj = ADE.CurrentModule</td>
</tr>
<tr>
<td>Remarks</td>
<td>Newly created objects are placed into CurrentModule; so, you should set CurrentModule before creating any new objects. Setting CurrentModule = Nothing means that no module is open, so all new objects are created in the top-level Module or Model of the currently opened model.</td>
</tr>
<tr>
<td>API errors</td>
<td>44 – “Module could not be set”</td>
</tr>
</tbody>
</table>

**DefaultDefTableRenderingStyle**

<table>
<thead>
<tr>
<th>Description</th>
<th>The default rendering style controlling how definition table values are transferred to and from ADE. All definition tables returned from CAObject::DefTable inherits these settings when they are first created.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>CARenderingStyle</td>
</tr>
<tr>
<td>Access</td>
<td>read/write</td>
</tr>
<tr>
<td>Usage</td>
<td>ADE.DefaultRenderingStyle.GeneralExpression = false</td>
</tr>
</tbody>
</table>

**DefaultRenderingStyle**

<table>
<thead>
<tr>
<th>Description</th>
<th>The default rendering style controlling how result values are returned from ADE. All CAObject instances inherit this rendering style when they are created.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>CARenderingStyle</td>
</tr>
<tr>
<td>Access</td>
<td>read/write</td>
</tr>
<tr>
<td>Usage</td>
<td>ADE.DefaultRenderingStyle.StringQuotes = 2</td>
</tr>
</tbody>
</table>
Chapter 5  ADE Server Class Reference

Class CAEngine

ErrorCode

Description Returns the error code generated by the last communication with the Analytica Decision Engine Server. The property ErrorCode should be checked after setting and retrieving critical CAEngine properties and calling CAEngine methods. An ErrorCode of zero indicates the last action was successful.

Data type integer
Access read
Usage Dim x As Integer
x = ADE.ErrorCode

ErrorText

Description Short text explanation of error from ErrorCode.
Data type string
Usage Dim x As String
x = ADE.ErrorText

Log

Description A record of all commands sent to the ADE typescript and the results received from those commands, when the Photo property is true.
Data type string
Usage Dim x As String
x = ADE.Log

OutputBuffer

Description A text string buffer that contains the result of the last typescript (i.e., using the Command property and Send method) interaction with the ADE.
Data type string
Usage Dim x As String
x = ADE.OutputBuffer

Photo

Description When Photo is True, ADE records all typescript commands and results into the Log property.
Data type boolean
Access read/write
Usage ADE(Photo = True
Remarks Setting Photo property to True slows down computation speed of the engine.

Methods

AddModule(fileName, merge)

Description Adds a module from file fileName into the CurrentModule. The merge parameter currently has no effect and should be set to True.
Parameters  
 fileName – string
 merge – Boolean

Return value  
 ModuleName – string

Usage  
 ModName = ADE.AddModule("C:\MYMOD\MYMOD.ANA", True)

API errors  
 39 – “Module could not be found”

CloseModel

Description  
 Closes the model.

Usage  
 ADE.CloseModel

CreateObject(objName, objClass)

Description  
 Creates a new Analytica object with identifier objName and class objClass in the CurrentModule and returns it as a CAObject.

Parameters  
 objName – string
 objClass – string

Return value  
 CAObject

Usage  
 Dim obj As CAObject
 Set obj = ADE.CreateObject("NewVar","Chance")

Remarks  
 objClass can be one of the following values: Decision, Variable, Chance, Constant, Index, Module, Objective, Determ, Alias, or Formnode.

API errors  
 40 – “Object could not be created”
 41 – “Invalid name for object”
 42 – “Object name already in use”
 48 – “Invalid object class”

CreateModel(modelName)

Description  
 Creates a new Analytica model with identifier modelName.

Parameters  
 modelName – string

Return value  
 Boolean (success or failure)

Usage  
 boolval = ADE.CreateModel("MyNewModel")

API errors  
 45 – “Model could not be created”

DeleteObject(obj)

Description  
 Deletes CAObject obj from the current model.

Parameters  
 obj – CAObject

Usage  
 Dim Obj As CAObject
 Set Obj = ADE.GetObjectByName("ObjToDelete")
 ADE.DeleteObject (Obj)

API errors  
 41 – “Invalid object”

GetObjectByName(objName)

Description  
 Returns an object of type CAObject for an existing Analytica object with identifier objName.

Parameters  
 objName – string

Return value  
 CAObject
Usage  Dim Obj As CAObject
      Set Obj = ADE.GetObjectByName ("MyObject")
      Set Obj = ADE.Get("MyObject") 'alternate equiv. form

API errors  41 – “Invalid name for object”

MonitorProcess(pid)

Description  Sets up a monitor thread inside ADE to detect the termination of the process with the indicated
process id, and to terminate the ADE process if the indicated pid terminates first.

Parameters  pid – An integer process id, which must be on the same machine as the ADE process.

      ADE.MonitorProcess( pid )

Remarks  It is useful to call this immediately after obtaining a CAEngine object, so that if you stop your pro-
gram prematurely while debugging, or your own code crashes without releasing the CAEngine
object, the ADE process will terminate along with your program.

Requires release 4.2.3 or later.

API errors  85 – MonitorProcess(pid)could not open the indicated process.
See also ADE.OutputBuffer for additional elaboration for why it failed.

OpenModel

Description  Reads a model from a disk file and opens it as the current model.

Parameters  FileSpec – string (the filename containing the model)

Return value  ModelName – string (actual model name)

Usage  modName = ADE.OpenModel ("C:\TMP\MYMODEL.ANA")

Remarks  Failure should be detected by checking whether the return value is ", not by checking for a zero
ErrorCode. It is possible that some errors or warnings might occur during loading, and is thus
reflected in the ErrorCode, ErrorText, and OutputBuffer properties, even though the load was
successful.

API errors  2 – Warning (but load was successfully completed)
            3 – Lexical error (load was only partially successful)
            4 – Statement error (load was only partially successful)
            39 – “Model could not be found”

ReadScript(filePath)

Description  Reads an Analytica script file and executes it.

Parameters  filePath – string

Usage  ADE.ReadScript ("C:\TMP\SCRIPT.MOD")

API errors  39 – “Script file could not be found”

ResetError

Description  Resets the error code, error text string associated with the error code, and the output buffer to
default values. This function is normally used internally, but could be useful in other circum-
stances as well.

Usage  ADE.ResetError

SaveModel(filePath)

Description  Saves the model to file filePath.

Parameters  filePath – string
Usage
ADE.SaveModel("C:\TMP\CHANGES.ANA")

API errors
46 – “Model could not be saved”
49 – “There is no model to save”

SaveModuleFile(modName, filePath)

Description
Saves module with identifier modName into file filePath.

Parameters
modName – string
filePath – string

Return value
Boolean (success or failure)

Usage
b = ADE.SaveModuleFile("Function_lib", "C:\TEMP\NEWMOD.ANA")

API errors
41 – “Invalid name for object”
46 – “Module could not be saved”

Send

Description
Sends the string contained in the Command property as a command to be executed by ADE. See the Analytica Scripting Guide for details of commands and syntax.

Return value
Boolean (success or failure)

API errors
1 – “Unimplemented”
2 – “Warning”
3 – “Lexical error”
4 – “Statement error”
5 – “Expression error”
6 – “Execution error”
7 – “System error”
8 – “Fatal error”
9 – “Undefined variable error”
10 – “Aborted”

SendCommand(command)

Description
Sends the string command property as a typescript command to be executed by ADE. See the Analytica Scripting Guide for details of commands and syntax.

SendCommand is a single method that is faster way to execute a typescript command than using the Send method. Using Send requires these two statements to execute a command.

```plaintext
ade.Command = "profile Va1"
b = ade.Send()
```

This can be done with a single SendCommand statement.

```plaintext
b = ade.SendCommand("profile Va1")
```

Return value
Boolean (success or failure)

API errors
1 – “Unimplemented”
2 – “Warning”
3 – “Lexical error”
4 – “Statement error”
5 – “Expression error”
6 – “Execution error”
7 – “System error”
8 – “Fatal error”
9 – “Undefined variable error”
10 – “Aborted”
Class CALicense

A CALicense object can be obtained directly, for example:

```java
license = new CALicense;
```

Or:

```java
license = CreateObject(“CALicense”)
```

The CALicense provides a method for instantiating a CAEngine, and provides details about why such an instantiation failed, which would otherwise not be available if you instantiate the CAEngine directly. It also provides some information about limitations in your license to use ADE.

A CALicense instance can be obtained even if your ADE license code is invalid, expired, etc. This makes it possible for your application to say "failed because .....”.

Properties

**AvailableLicenseInstances**

<table>
<thead>
<tr>
<th>Description</th>
<th>Number of additional ADE instances that can still be instantiated using the current license, beyond those that are already running.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>integer</td>
</tr>
<tr>
<td>Access</td>
<td>read</td>
</tr>
<tr>
<td>Usage</td>
<td>nAvail = license.AvailableLicenseInstances</td>
</tr>
<tr>
<td>Remarks</td>
<td>Your license to use ADE might or might not limit the number of instances of ADE that can be simultaneously active on the same computer. For licenses that do impose a limit, this property how many additional ADE instances (equivalent to the number of CAEngine instances) can be created on this computer within the limit imposed by the license.</td>
</tr>
</tbody>
</table>

**CanUseOptimizer**

<table>
<thead>
<tr>
<th>Description</th>
<th>Indicates whether your ADE license allows your models to make use of the Optimizer. If you don’t have this ability, then models that use LpDefine, QpDefine or NlpDefine functions cannot perform those optimizations within ADE. This flag makes it possible to detect that limitation before actually starting your application.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>boolean</td>
</tr>
<tr>
<td>Access</td>
<td>read</td>
</tr>
<tr>
<td>Usage</td>
<td>if (license.CanUseOptimizer){ ... }</td>
</tr>
</tbody>
</table>

**errorCode**

<table>
<thead>
<tr>
<th>Description</th>
<th>Status code (reason for failure) from the previous method call. In particular, after calling the CALicense.NewCAEngine method, this provides information about the cause of the failure. Descriptive text for any error code can be obtained using the ErrorCode property. Some codes that could encountered (this is not comprehensive) include:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type</td>
<td>integer</td>
</tr>
<tr>
<td>71</td>
<td>“The maximum number of CAEngine instances allowed are already in use”</td>
</tr>
<tr>
<td>72</td>
<td>“Invalid license code”</td>
</tr>
<tr>
<td>73</td>
<td>“Stale license code”</td>
</tr>
<tr>
<td>74</td>
<td>“Expired license code”</td>
</tr>
<tr>
<td>75</td>
<td>“No ADE license code is present”</td>
</tr>
<tr>
<td>76</td>
<td>“Not an application license code” (from SetApplicationLicenseCode method)</td>
</tr>
</tbody>
</table>
Access read
Usage `errCode = license.ErrorCode`

**ErrorText**

**Description** Status text describing the reason for a failure in the previous method call. In particular, after calling the `CALicense.NewCAEngine` method, this provides information about the cause of the failure.

**Data type** string

**Access** read

**Usage** `errDescription = license>ErrorText`

**MaxLicenseInstances**

**Description** Total number of ADE instances allowed on current license, including any currently running.

**Data type** integer

**Access** read

**Usage** `nAvail = license.MaxLicenseInstances`

**Remarks** Your license to use ADE might or might not limit the number of instances of ADE that can be simultaneously active on the same computer. For licenses that do impose a limit, this property provides access to what that number is (which will be greater than 0). If you have no limit, this is zero.

**RlmHostId**

**Description** The Reprise License Manager host id (used for license activation and validation) for the computer running the ADE process.

**Data type** string

**Access** read

**Usage** `hostId = License.RlmHostId`

**Remarks** Requires build 4.2.3 or later.

**RlmPath**

**Description** The path used by the Reprise License Manager when searching for a valid license.

**Data type** string

**Access** read

**Usage** `path = License.RlmPath`

**Remarks** Requires build 4.2.3 or later.

**RlmUserId**

**Description** The Reprise License Manager user id for the computer running the ADE process.

**Data type** string

**Access** read

**Usage** `userId = License.RlmUserId`

**Remarks** Requires build 4.2.3 or later.
Methods

NewCAEngine

Description
Attempts to create an instance of CAEngine. If this is not possible, perhaps due to a limitation in your ADE license, the ErrorCode and ErrorText properties are set to indicate the reason for the failure.

Parameters
none

Return value
CAEngine, or Null upon failure

Usage
ade = license.NewCAEngine

API errors
See description for ErrorCode property.

SetApplicationLicenseCode

Description
Specifies an ADE license code that is to be used for the instantiation of a CAEngine when CALicense.CAEngine is called. When this is used, a valid ADE license code does not need to be stored in the system registry, and ADE runs according to the licensed features of the specified license code, which might be different from the license code used when ADE was installed (if any). This only accepts “ADE application license codes.” The license code you use when you install ADE is not an application license code. Application license codes are obtained through special arrangement with Lumina for applications that have been licensed through Lumina for redistribution.

Parameters
licenseCode -- string

Return value
CAEngine, or Null upon failure

Usage
license.NewCAEngine("ABCD-1234-EFGH-I5J6-KLMN-7890")

API errors
See description for ErrorCode property.

Class CAObject

Properties

ClassType

Description
Contains the type of the Analytica object.

Data type
string

Access
read/write

Usage
classType = obj.ClassType

Remarks
ADE currently supports the following types of Analytica objects: decision, chance, constant, index, module, and variable.

DefinitionType

Description
Provides quick information about how a variable is defined.

Data type
integer

Access
read

Return value
-1 = Definition not parsed (e.g., no definition)
0 = General expression
1 = Edit table
2 = Prob Table
3 = Deterrn Table
4 = Sub-Table
5 = List
6 = List of Labels
7 = Choice

Usage  defType = obj.DefinitionType

MethodEvaluationTime

Description  A maximum time limit for evaluations, in milliseconds. If exceeded in any given call, the computation aborts. This can cause calculations by the methods Result, ResultTable, or Evaluate to terminate before the computation is complete.

Data type  integer
Access  read/write

Usage  obj.MethodEvaluationTime = 30000 /*ms*/
        tab = obj.ResultTable
        if (ade.ErrorCode == 77) { /*timeout occurred*/ }

Name

Description  Contains the name given to the Analytica object.

Data type  string
Access  read/write

Usage  obj.Name = "NewName"

API errors  41 – "Invalid name for object"

RenderingStyle

Description  Contains a CARenderingStyle object that controls how data is returned from Analytica. This property is inherited from the DefaultRenderingStyle property of CAEngine when the object is first instantiated. Its settings control how data is returned from CAObject::Result and CAObject::GetAttribute. Also, the settings are inherited by any CATable created from the object by the Evaluate or ResultTable methods.

Data type  CARenderingStyle
Access  read/write

Usage  obj.RenderingStyle.StringQuotes = 0

ResultType

Description  Specifies the treatment of uncertainty in the value obtained using the Result or ResultTable properties:
0 – Mid value (default)
1 – Mean
2 – Sample
3 – PDF
4 – CDF
5 – Statistics
6 – Confidence Bands

Data type  short
Access  read/write

Usage  CAObject.ResultType = 1
Methods

CreateDefTable(indexList)

**Description**
Creates an input table object in the definition attribute of the specified Analytica object with dimension specified by the `indexList`. The IndexList parameter must contain an array of identifiers of existing index variables (identical in form to the IndexNames method of class CATable). The number of indexes in indexList determines the number of dimensions of the table. One index can be Self, meaning that one of the dimensions are indexed by the Indexvals attribute of this variable. should be one of the entries in the array. Initially, the input table object’s array is filled with null elements, which can be changed using the SetDataByElements and SetDataByLabels methods of the class CATable.

**Parameters**
- indexList – array of strings

**Return value**
Boolean (success or failure)

**Usage**
Var.CreateDefTable (IndexList)

**API errors**
- 25 – “Subscripts cannot be accessed”
- 26 – “Lower bound of subscript array inaccessible”
- 27 – “Upper bound of subscript array inaccessible”
- 28 – “Must specify at least one element in table”
- 32 – “Index object not found”

DefTable

**Description**
Gives object of class CATable containing the input table for an Analytica variable, or Nothing if the variable was not defined as an input table.

**Data type**
CATable

**Access**
read/write

**Usage**
Dim tab As CATable
Set tab = obj.DefTable

**API errors**
- 34 – “Definition table not found”

Evaluate(expr)

**Description**
Parses and evaluates an Analytica expression expr.

**Parameters**
- expr – string

**Return value**
CATable

**Usage**
dim tab As CATable = 
obj.Evaluate("Sum(Revenue,Division)")

**API errors**
- 35 – “Attribute could not be retrieved”

GetAttribute(attribName)

**Description**
Gets the value of attribute attribName of the object.

**Parameters**
- attribName – string

**Return value**
variant

**Usage**
X = obj.GetAttribute("definition")

**API errors**
- 35 – “Attribute could not be retrieved”

PictureToFile(fileName, mimeType)

**Description**
Causes ADE to retrieve CAObject object’s picture, if any, and save it to file fileName, in the format specified by mimeType.
Return value: Boolean (success)

Parameters:
- `fileName` – string
- `mimeType` – string (usually "image/jpeg", "image/bmp", "image/tiff", or "image/png")

Usage:
```plaintext
obj = ade.Get("Pil");
bSuccess = obj.PictureToFile( @"C:\Temp\myPict.jpg","image/jpeg")
```

**PictureToStream(stream, mimeType)**

Description: Causes ADE to retrieve CAObject object's picture, if any, and send it to the stream specified by `stream`, in the format specified by `mimeType`.

Return value: Boolean (success)

Parameters:
- `stream` – string
- `MimeType` – string (usually "image/jpeg", "image/bmp", "image/tiff", or "image/png")

Usage:
```plaintext
dim outStream as MyStreamWrapper = _
    new MyStreamWrapper(Response.OutputStream)
    bSuccess = obj.PictureToStream( outStream,"image/jpeg")
```

**Result**

Description: Gives the result value of the object as a single value (not a table). ADE first evaluates the value if it has not already been evaluated. If the value is an array, it returns it as a string of comma-delimited elements.

Data type: variant

Access: read

Usage:
```plaintext
Dim x
X = obj.Result
```

API errors: 37 – "Could not retrieve result"

**ResultTable**

Description: Gives the value of the object as a CATable, with zero or more dimensions, or Nothing if the object cannot be evaluated. ADE first evaluates the variable if necessary.

Data type: CATable

Access: read

Usage:
```plaintext
Dim res As CATable
Set res = obj.ResultTable
```

API errors: 38 – "Could not get result table"

**SetAttribute(attributeName, value)**

Description: Sets the attribute `attributeName` of the object to `value`. It returns true if successful or false if not.

Parameters:
- `attributeName` – string
- `value` – Variant

Return value: Boolean

Usage:
```plaintext
bool = obj.SetAttribute ("definition","A/B")
```

API errors: 36 – "Attribute could not be set"
Class CATable

Properties

GraphHeight
Description Controls the height of the graph image returned by GraphToStream or GraphToFile.
Data type integer (number of pixels)
Access read/write
Usage tab.GraphHeight = 500

GraphWidth
Description Controls the width of the graph image returned by GraphToStream or GraphToFile.
Data type integer (number of pixels)
Access read/write
Usage tab.GraphWidth = 600

NumDims
Description The number of dimensions of the table (zero if it is a scalar with no dimensions).
Data type short
Access read
Usage x = tab.NumDims

RenderingStyle
Description Contains a CARenderingStyle object that controls how atomic values are interpreted when transferred to and from table cells. Definition tables inherit this property from the DefaultDefTableRenderingStyle property of CAEngine. Result table inherits this property from the CAObject that created the table.
Data type CARenderingStyle
Access read/write
Usage tab.RenderingStyle.NumberAsText = true

ResultType
Description Contains the type of result that was computed, and controls the type of result computed if the table is updated. Possible value are the same as for CAObject::ResultTable.
Data type short
Access read/write
Usage x = tab.ResultType

TableType
Description This property holds the type of the table (*D* for a definition table, and *V* for a result table)
Data type string
Access read
Usage x = tab.TableType
Methods

AtomicValue

Description
Retrieves the scalar value from a zero-dimensional CATable object. A zero-dimensional table results when a result is not an array, or when you call Slice or Subscript on a one-dimensional array.

Return value
variant

Parameters
none

Usage
x = tab.AtomicValue

GetDataByLabels(indexLabels)

Description
Retrieves the value of an input table cell according to indexLabels, which specify the label for each index of the table in order.

Return value
variant

Parameters
Values of indexes (Variant); the number of elements in Variant must be equal to NumDims.

Usage

IndexLabs (1) = 3
IndexLabs (2) = "green"
W = Var.DefTable.GetDataByLabels (IndexLabs)

Or

IndexLabs (1) = 3
IndexLabs (2) = "green"
W = Var.ResultTable.GetDataByLabels (IndexLabs)

If the table has only one dimension, the parameter need not be an array:

W = Var.ResultTable.GetDataByLabels ("green")

API errors
24 – “Subscripts must be an array of variants”
25 – “Subscripts cannot be accessed”
26 – “Lower bound of subscript array inaccessible”
27 – “Upper bound of subscript array inaccessible”
28 – “Must specify at least one element in table”
30 – “Position does not exist”

GetDataByElements

Description
Retrieves the value of input table cell according to index values.

Return value
variant

Parameters
Index values (variant), number of elements in the variant must be equal to NumDims.

Usage

IndexPtrs (1) = 1
IndexPtrs (2) = 2
W = Var.DefTable.GetDataByElements (IndexPtrs)

Or

IndexPtrs (1) = 1
IndexPtrs (2) = 2
W = Var.ResultTable.GetDataByElements (IndexPtrs)

If the table is one-dimensional, then an array is not needed:

W = Var.ResultTable.GetDataByElements (1)

API errors
24 – “Subscripts must be an array of variants”
25 – “Subscripts cannot be accessed”
26 – “Lower bound of subscript array inaccessible”
Chapter 5 ADE Server Class Reference

Class CAEngine

27 – “Upper bound of subscript array inaccessible”
28 – “Must specify at least one element in table”
29 – “Position specified is out of bounds”
30 – “Position does not exist’
31 – “Illegal Position Specified In Table”

GetIndexObject
Description Retrieves an index object by its name
Return value CAIndex
Parameters index name: string
Usage dim AI as CAIndex
     Set AI = AObj.GetIndexObject (IndexName)
Remarks If ObjName is not valid the method returns Nothing.
API errors 32 – “Index object not found”

GetSafeArray
Description Retrieves the CATable as a safe array (i.e., a Visual Basic array). The ordering of the dimensions is controlled by the SetIndexOrder method. The elements of each dimension are indexed 1 to N, where N is the size of each index.
Return value Array
Usage dim Var As CAObject
     Dim curTable
     curTable = Var.GetSafeArray

GraphToFile(fileName, mimeType)
Description Creates a graph image of the data contained in the CATable object formatted using the mimeType and writes it to file fileName. It uses attribute settings for the CAObject from which the CATable was obtained to control graph settings, uncertainty settings, and number format. The GraphWidth and GraphHeight properties control the size of the graph image in pixels.
Return value Boolean (success)
Parameters fileName – string
     mimeType – string (usually "image/jpeg", "image/bmp", "image/tiff", or "image/png")
Usage tab.GraphWidth = 350
     tab.GraphHeight = 200
     b = tab.GraphToFile( "C:\data\trends.jpg","image/jpeg")

GraphToStream(stream, mimeType)
Description Creates a graph image of the data contained in the CATable object formatted using the mimeType, and writes it to stream, a Windows IStream.
Note: Note: An IStream is not interchangeable with a .NET System.IO.Stream object (including a Response.OutputStream object in ASP.NET). A wrapper class is necessary for converting between these. The size of the image in pixels is controlled by the GraphWidth and GraphHeight properties of the table.
Return value Boolean (success)
Parameters stream – string
     MimeType – string (usually "image/jpeg", "image/bmp", "image/tiff", or "image/png")
Usage tab.GraphWidth = 350
IndexName(IndexNumber)

Description  Takes one parameter, **IndexNumber**, and returns the name of the corresponding index for CATable.

Return value  string

Parameters  **IndexNumber** – short int

Usage  dim string as indexTitle = Var.DefTable.IndexName (1)

IndexNames

Description  Returns the names of the indexes of the table as an array. Use indexes in this order when using the **GetDataBy** and **SetDataBy** methods to get or set elements of the table. You can change the order with the **SetIndexOrder** method.

Data type  string array with dimension from 1 to object’s **NumDims** property

Access  read

Usage  Dim names(k) of String = Var.DefTable.IndexNames (k)

PutSafeArray

Description  Replaces the current table represented by this object with another table of the same dimensions.

Return Value  CATable

Parameters  The table (Visual Basic array) that replaces the current table.

Usage  Dim Var As Object
        Dim TheArray
        TheArray = Var.GetSafeArray
        Var.PutSafeArray (TheArray)

API errors  24 – “Subscripts must be an array of variants”
            50 – “Safe-array has incorrect size or number of dimensions”

SetDataByLabels

Description  Sets the value of an input table cell according to its index labels.

Return value  Boolean (success or failure)

Parameters  Cell value (Variant), values of indexes (Variant), number of elements in this variant must be equal to **NumDims**.

Usage  IndexVals (1) = 3
        IndexVals (2) = ‘green’
       RetVal = Var.DefTable.SetDataByLabels (W, IndexVals)

If the table is one-dimensional, then an array is not needed:

W = Var.DefTable.SetDataByLabels (W, "green")

API errors  24 – “Subscripts must be an array of variants”
            25 – “Subscripts cannot be accessed”
            26 – “Lower bound of subscript array inaccessible”
            27 – “Upper bound of subscript array inaccessible”
            28 – “Must specify at least one element in table”
            30 – “Position does not exist”
            31 – “Illegal position specified in table”
SetDataByElements(value, indexVals)

**Description**
Sets the input table cell specified by `indexVals` to value. `indexVals` must contain a label for each index of the table, so the number of labels must equal `NumDims`. If the table has just one dimension, `indexVals` can be the label for that one index rather than an array of labels.

**Return value**
Boolean (success or failure)

**Parameters**
- `value`: Variant
- `indexVals`: Variant

**Usage**

```
IndexPtrs (1) = 1
IndexPtrs (2) = 2
RetVal = Var.DefTable.SetDataByElements (W, IndexPtrs)
```

If the table is one-dimensional, then an array is not needed:

```
W = Var.DefTable.SetDataByElements (W, 1)
```

**API errors**
24 – “Subscripts must be an array of variants”
25 – “Subscripts cannot be accessed”
26 – “Lower bound of subscript array inaccessible”
27 – “Upper bound of subscript array inaccessible”
28 – “Must specify at least one element in table”
29 – “Position specified is out of bounds”
31 – “Illegal position specified in table”
51 – “Element position is non-numeric”

SetIndexOrder(indexNames)

**Description**
Sets the order of the indexes in the table to the order of `indexNames`, which must contain the names of only and all the indexes of the table, assuming it has more than one index. This order determines the order used by `SetDataByElements`, `SetDataByLabels`, `GetDataByElements`, and `GetDataByLabels` to access a cell in a table.

**Return value**
Boolean (success or failure)

**Parameters**
- `indexNames` – array of strings

**Usage**

```
IndexVals (1) = ‘X’
IndexVals (2) = ‘Y’
RetVal = Var.DefTable.SetIndexOrder (W, IndexVals)
```

**API errors**
24 – “Subscripts must be an array of variants”
25 – “Subscripts cannot be accessed”
26 – “Lower bound of subscript array inaccessible”
27 – “Upper bound of subscript array inaccessible”
28 – “Must specify at least one element in array”
52 – “Specified name is not an index of the array”

Slice(indexObj, n)

**Description**
Returns the `n`th slice of the table over index `indexObj`. The result is a new `CATable` object with one fewer dimensions than the table to which it is applied. When used on a `DefTable`, the sliced `DefTable` acts as a `SubTable`, changing elements in the slice of the original table.

**Parameters**
- `indexObj`: CAObject
- `n`: Integer – the 1-based slice position along index

**Return value**
`CATable`

**Usage**

```
dim In1 as CAIndex = tab.GetIndexObject("In1")
dim subTab as CATable = tab.Slice( In1, 1 )
```

Subscript(indexObj, label)

**Description**
Returns a slice of a table for which index `indexObj` is equal to `label`. It returns a new `CATable` object with one fewer dimension than the original table. When used on a `DefTable`, the sliced `DefTable` acts as a `SubTable`, changing elements in the slice of the original table.
Class CAEngine

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>indexObj</td>
<td>CAObject</td>
<td>CAObject</td>
</tr>
<tr>
<td>label</td>
<td>variant</td>
<td>variant</td>
</tr>
</tbody>
</table>

Return value

<table>
<thead>
<tr>
<th>Return value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CATable</td>
<td>CATable</td>
</tr>
</tbody>
</table>

Usage

```vbnet
dim In1 as CAIndex = tab.GetIndexObject("In1")
dim subTab as CATable = tab.Slice( In1, "SomeLabel" )
```

Update

Description

For definition tables: Updates an existing input table in the definition attribute of an Analytica object. Use this method after setting one or more SetDataBy methods to direct the API to send the new table data to the Analytica Decision Engine Server.

For result tables: Retrieves an updated version of the result table from the Analytica Decision Engine Server.

Return value

Boolean (success or failure)

Usage

```vbnet
Var.DefTable.Update
```

Remarks

Use the CreateDefTable method to replace the current definition attribute of an Analytica object with an input table.

Class CAIndex

Properties

IndexElements

Description

Returns the number of elements in the index.

Data type

integer

Access

read

Usage

```vbnet
x = theIndex.IndexElements
```

Name

Description

Contains the name given to the Analytica index.

Data type

string

Access

read/write

Usage

```vbnet
theName = theIndex.Name
```

API errors

41 – “Invalid name for object”

RenderingStyle

Description

Contains a CARenderingStyle object that controls how values are returned from GetValue-ByNumber.

Data type

CARenderingStyle

Access

read/write

Usage

```vbnet
theIndex.RenderingStyle.StringQuotes = 1
```
Methods

GetNumberByValue

**Description**
Returns the position of an index label in an index.

**Parameters**
- **Value** – variant

**Return value**
integer

**Usage**
\[ n = \text{theIndex}.\text{GetNumberByValue} \ (\text{Value}) \]

**API errors**
22 – “Value not found in index”

GetValueByNumber

**Description**
Returns the index label at the specified position in the index.

**Parameters**
- **Number** – integer

**Return value**
variant

**Usage**
\[ W = \text{theIndex}.\text{GetValueByNumber} \ (\text{Number}) \]

**API errors**
23 – “Illegal position in index”

Class CARenderingStyle

Properties

GeneralExpression

**Description**
Determines how string values are interpreted when they are written to a definition table. When True (default), a string is taken to be an expression, which must parse to be a valid expression. When False, a string value is stored as a literal string. For example, the value “Pi” would be interpreted as the identifier \( \text{Pi} \) when **GeneralExpression** is true, and would thus evaluate to 3.141592654, but the same string would be interpreted as a literal character string when **GeneralExpression** is false, and would evaluate to two-character textual string.

**Data type**
Boolean

**Access**
read/write

**Usage**
\[ \text{deftab.RenderingStyle}.\text{GeneralExpression} = \text{false} \]

FullPrecision

**Description**
When True, a numeric value is rendered as text (see the **NumberAsText** property below) and has the maximum number digits needed to represent the number at full precision (usually 16). If False, a loss of precision does not occur.

**Data type**
Boolean

**Access**
read/write

**Usage**
\[ \text{dim res As CATable = obj.Evaluate("sqrt(2)")} \]
\[ \text{res.RenderingStyle}.\text{NumberAsText} = \text{true} \]
\[ \text{res.RenderingStyle}.\text{FullPrecision} = \text{false} \]
\[ \text{dim s As String = res.AtomicValue } \text{ returns "1.414" } \]
\[ \text{res.renderingStyle}.\text{FullPrecision} = \text{true} \]
\[ s = \text{res.AtomicValue } \text{ returns "1.4142135623731" } \]
NumberAsText

Description: Controls whether numeric results or numeric table cell definitions are returned as floating point numbers or as formatted strings. When true, the number format for the current object controls how the number is formatted as a string (except that the FullPrecision property can override the number of digits in the number format).

Data type: Boolean
Access: read/write
Usage: deftab.RenderingStyle.NumberAsText = true

ReferenceAsText

Description: Some Analytica expressions can evaluate structured value (such as a tree) containing references. This property controls whether references are returned as CATable objects (containing the de-referenced value), or rendered as text. By default, they are returned as CATable objects. Note that in Analytica, a reference is treated as atomic, even though its dereferenced value can be array valued.

Data type: Boolean
Access: read/write
Usage:
```plaintext
obj.SetAttribute("definition", "\(A^t\)")
def res as CATable = obj.Evaluate("\(A^t\)")
res.RenderingStyle.ReferencesAsText = false
def derefdVal as CATable = res.AtomicValue
```

SafeArrayLowerBound

Description: The lower bound for safe arrays returned by CATable::GetSafeArray. Default is 1.

Data type: Integer
Access: read/write
Usage: ADE.DefaultRenderingStyle.SafeArrayLowerBound = 0

StringQuotes

Description: Controls whether textual values are returned with explicit quotation marks surrounding a string, according to its value:
- 0 = no quotes around strings, e.g., 0.25
- 1 = single quotes, e.g., '0.25'
- 2 = double quotes, e.g., "0.25"

When NumberAsText is true, with no quotation marks around string values, the numeric value 0.25 and the string containing the four characters "0.25" would be indistinguishable. If you want to be able to distinguish them, set the value of StringQuotes to 1 or 2.

Data type: Short:
- 0 = no quotes
- 1 = 'single quotes'
- 2 = "double quotes"
Access: read/write
Usage: deftab.RenderingStyle.StringQuotes = 2

UndefValue

Description: This property specifies the value returned when the Analytica value is Undefined. By default, ADE returns the special value variant Empty — for example, when GetAttribute is applied to an attribute that was not set. Some scripting languages cannot manipulate the value Empty. In this case, you can set UndefValue to something more convenient, such as Null or the empty string.
Data type  Variant
Access     read/write
Usage      ADE.DefaultRenderingStyle.UndefValue = Null

HandleFormat
Description Controls how a Handle (a pointer to an Analytica object) is returned. A Handle can occur in a definition cell of a table if that definition consists of a single identifier. There are also some rare Analytica expressions that can produce a Handle in a result. If HandleFormat = 0, it returns the identifier of the Analytica object as a string; if 1, a CAObject for the Analytica object; or if 2, the title of the object as a string.
Data type  Short:
           0 = identifier
           1 = CAObject
           2 = title
Access     read/write
Usage      deftab.RenderingStyle.HandleFormat = 1
## Error Codes

This appendix provides you with the complete list of ADE error messages.
